We can ship these outfits from Syracuse, N. Y., Mechanic Falls, Maine, Medina, O., or Des Moines, Iowa, so the freight will be low.

GLEANINGS ONE YEAR, and Mantel Clock, both for \$4.50. Can ship clocks from Cleveland or New York City.

LAST OF ALL, if you don't want any of these Clubbing Offers, send us 50 cents for GLEANINGS the remainder of the year.

The A. I. Root Company
MEDINA, OHIO.

GENERAL ITEMS

Bees Doing Nicely.

Our bees are doing nicely. We started last spring with 4 colonies, and increased to 10; several went away. Honey here is principally gathered from alfalfa, and it is nice; heart's-ease is next. We took 400 pounds of comb honey, all in one-pound sections. We always leave them some in the super; I look to-day and found some out of food, and gave them more. I love to work with them. Mrs. M. J. BEVINGTON, Jewell Co., Kan., April 15.

Very Backward Spring.

We are having a very cool, backward spring, the thermometer registering 31 degrees yesterday morning. The fruit-crop in this section will be a total failure, and box-hive bee-keepers will lose very heavily. Last June and July the honey-flow was good, and they (the box-hive men) robbed about July 20; the fall was very wet, so that no honey was gathered after July, and their bees are now destitute of stores, and unless the weather changes right away to warm and fair, the loss will be heavy.

This spring is the fourth cool and backward one. I wonder if it will never change. The June and July flow, lasting from 40 to 60 days, rarely ever fails, and the man whose bees are in good condition the first of June is reasonably sure of a crop every year. J. M. CUTTS, Montgomery Co., Ala., April 10.

Hard Winter on Bees.

It has been a hard winter on bees in this part of Iowa. Almost all died that were left on the summer stands without protection. I put 150 colonies into the cellar last fall, and took them out April 11; they were all alive, tho some of them were weak and the hives spotted badly.

CHARLES BLACKBURN,
Buchanan Co., Iowa, April 15.

Turpentine for Stings, Etc.

Rain or no rain, my bees are piling in honey from orange-bloom, which has been on about two weeks, and will last a week or 10 days yet. Then alfalfa will begin to bloom (there being hundreds of acres along the Riverside canal.) Of course I do not expect to get any orange honey, for the hives were nearly empty to start with, but the bees will store for themselves some of the best honey the world produces.

Tell those who are anxious for an antidote for bee-poison, to try spirits of turpentine. Scrape off the sting and apply the turpentine at once, and no itching or swelling will be the result. H. M. JAMESON, Riverside Co., Calif., April 11.

Sorghum-Making and Bees.

I saw a solicitation last fall in the Bee Journal asking some one to give experience on sorghum-making. I had an experience last fall which was very dear to me. I raised quite a quantity of cane last summer, and in the fall—as is the custom in this country, and I suppose in all other countries where they raise the "stuff"—I undertook to make the molasses, just at a season when there was no bloom for the bees to work on—rather earlier than common, just before the wild aster came into bloom.

We began to grind out the juice, and such another time you never saw! Instead of grinding "cane," as it is called, we were grinding bees. It did not stop here. When we began to boil the juice we began to boil the bees, and oh, my! you never saw such a mess.

I kept on this way a day or so, until the

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | | | | |
|-----------------------|------|--------|--------|------|
| Sweet Clover, melilot | 5lb | 10lb | 25lb | 50lb |

They are so simple and perfect that one cannot fail with them. They hatch every fertile egg. Sold under a positive guarantee. **FREE** illustrated catalogue. **Mascotte Incubator & Lumber Co., Box 11, Bedford, Ohio.**

Please mention Bee Journal when writing.

TWO WAGONS AT ONE PRICE.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn-fodder, wood, stones, etc. The man who already has a wagon may have one of these low

handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad-faced tire, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments. You thus virtually have two wagons at one price. Write to the Electric Wheel Co., Box 16, Quincy, Illinois, for their catalogue, which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

The Midland Farmer

SEMI-MONTHLY.

The representative modern Farm Paper of the Central and Southern Mississippi Valley. Page departments to every branch of Farming and Stock-Raising. Plain and Practical. Seasonable and Sensible. bees literally besteged the works, worse than the Spaiiards at Santiago. I began to reconnoiter the apiary, to devise some plan whereby I could get some advantage of the bees, if possible, but all to no purpose—they outwitted me.

So the next thing was to devise some plan to keep them in the hives, if possible. I got slats (the bottom pieces to Langstroth frames), and took a small nail and tacked it on the mouth or entrance of the hives, in the morning, before the bees were "up," leaving, as I thought, space enough for them to get air, and went to my work again, thinking I had struck a bonanza. But along about noon the bees were storming the castle again by making another charge on the mill. I stood them as long as I could, which was about 3 o'clock in the evening. By this time I was getting "hot" again, and said to myself, "I will keep you in next time."

When I went to the hives in the evening I found the honey running out of the hives in torrents. I hastily took the strips off, and found five of the best colonies just as dead and as wilted as if I had held them over the fire. Suffice to say, I will never try it again.

No bee-keeper should "monkey" with cane-raising. I had one queen I had imported from Italy which I examined hastily, and found it all right, and was truly glad it was no worse than it was. The bees crowded in the space I had left, and shut off all the air, and you would readily know the consequence. I lost 5 out of 50 colonies.

JOSEPH A. PIERSON.

Braxton Co., W. Va., April 3.

Bees in Fine Condition, Etc.

Bees wintered well in this locality as far as I know. I put 64 colonies into the cellar Nov. 22, and took them out about the first of March. I took 60 out alive, and they are in fine condition at present. I tried indoor wintering on a small scale, and lost 5

out of 9 colonies, and those 4 that are left aren't of much account. I prefer cellar-wintering, every time.

We have had some awfully cold weather this winter, and no snow. It is quite likely the clover is frozen. I have examined several stalks of Alsike clover, and it looks as if it were frozen. Bees have done nothing so far here (March 28). I saw them work on soft maple March 14 three or four years ago, but we generally get good weather for bees about April 1st. So far we have had no sign of spring. We had about three inches of snow yesterday, and the ground looks as bare as it was in January.

Eight years ago, when I started in bee-keeping, the farmers around here always sowed red clover on lowland, and then they would claim that they could not raise clover. This set me to thinking how I could help my neighbors, and at the same time help myself. So I bought a lot of Alsike clover seed, and got some of my neighbors to try it, and I tried some of it myself on some of the wettest land that we had. This land was too wet for timothy, and this clover has not failed to produce a crop. Some years ago we had such a wet season that some of the land was under water six weeks, and this was in the summer (May and June), and this clover was all right when the water was gone, and we made hay from that land in July.

There is another point that I find that farmers don't seem to understand very well, and that is, the fertilization of plants. There are not enough bumble-bees to fertilize the red clover, while the honey-bee works on the Alsike clover. It is this working by the bees that makes it yield seed the first and second crops, and it is those two crops of seed every year that keeps up a good stand when we have cold and wet weather, when apple, plum, raspberry, and all other fruits are in bloom so the bees cannot work on the bloom. We generally don't get much fruit, still there are some people that think bees are a nuisance, but they don't think that nice fruit which the bees have helped them to get is a nuisance.

My last year's honey crop was about 400 gallons, which I sold long before the new year arrived. I have over 60 colonies that I am going to run for extracted honey, because I can sell that the best. I am going into the bees a little heavier in the future, because I have found some one that is willing to help me—a loving wife. (There ought always to be two to keep bees rightly!)

The American Bee Journal ought to be taken by every man and woman that keeps bees.

I am of the opinion that honey-dew is produced by insects in this part of the country. I have seen just as clear stuff as water on the leaves of common hedge, and on examination I could find the insects. Last spring our plum trees were just alive with insects, and I found my bees working on the leaves of those trees. The stuff was dark in color. Later in the summer I found the bees working on acorns, and on examination I found a grub in each one of them. This stuff lookt like pine tar, and was not fit to eat.
JACOB WIRTH.

Henry Co., Ill., March 31.

That Tired Feeling!

These are our stretching days. We yawn and groan and twist ourselves with threatening danger to our backbone and the general anatomy! Why? Because spring has come, and Nature is making startling efforts to loosen our joints into greater activity, as the buds are pushed out for their fruitful mission.

The winter's cold has, in a manner, shriveled us, as all things else with life, and now the warm sun and balmy air have come to loosen our joints, to clear the brain, to stir the blood for the greater activities that await us from now until the mercury shall again contract into its little round receptacle at the lower end of the thermometer, which has patiently stood outside, thru the vicissitude of all weather, to remind us of the frequent and varied changes, from tor-

rid heat to arctic cold, as the seasons have come and gone. Thou limber up the hinges and bring yourself into a happy frame of mind for the work that must be done—work that if intelligently accomplished will prove our physical as well as financial blessing.

"Oh, but I feel sort of rheumatically these days—can't spunk up like I used to, you know," says our elder Uncle Billy. Just so, I understand your feelings. The muscles have become infiltrated with a kind of poison termed "uric acid," which, from want of sufficient exertion to throw it off, makes the legs and arms and back stiff, lame and sore. But, say, Uncle Billy, you don't have to seek far for the best remedy which a kind Nature provides. Just look around for those early yellow dandelions—the bees'll take you right to 'em. Dig up a hatful of the roots and leaves and get mother to make you a gallon of good strong tea of them, and take a cupful each night and morning for a week or two—drink it hot, mind you—and see where all those pains and aches have gone to! Why, you'll feel like cutting the "pigeon wing" as in days of long ago.

Well, here's to you! DR. PEIRO.

2-frame Nucleus with Untested Queen, \$2.25.

MARSHFIELD, WISCONSIN.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, April 18.—Best grades of white, 13c; off in color, etc., 11@12c; light amber, 10@11c; dark amber and mixt buckwheat, 7@9c. Extracted, clover, 8c; other grades of white, 7@7½c; ambers and dark, 6@7c. Beeswax, 27c.

Sales are in a small way, as the time of year is with us which usually sees the close of active sales. Owing to the inclement weather which has cut off the early fruits and vegetables the honey market has benefited, so that all of the white comb is nearly disposed of. There is quite a quantity of dark and undesirable comb being offered.
R. A. BURNETT & CO.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10@11c; dark and amber, 8@9c. Extracted in fair demand without change in price. Beeswax, 25@26½.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey.
M. H. HUNT.

NEW YORK, April 19.—Fancy white, 12c; No. 1 white, 10@11c; amber, 9c; buckwheat, 7@7½c. Extracted in good demand at unchanged prices. Beeswax quiet at 27c.

Our market is well cleaned up on comb honey. There is a fair demand, especially for white.
HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, April 5.—White comb, 10@10½c; amber, 7½@9c. Extracted, white, 7½@9c; light amber, 6½@7c. Beeswax, 26½@27c.

Beyond a small jobbing trade, mainly out of supplies in second hands, there is nothing to record in the way of business. There are only moderate supplies, and these are mainly comb. Values are steady. It is too early to get definite information concerning coming crop, but it is not likely to prove large in this State.

BOSTON, April 18.—Fancy white, 13c; No. 1, 11@12c; A No. 1, 10@11c; light amber, 9c. Extracted, stocks about cleaned up. Nominal price for white, 8c; for light amber, 7c. Beeswax, very light stocks; selling at 27@28c.

Naturally the demand for honey is gradually growing less, and although stocks on hand are not large, still the demand is so small that the general feeling is weak and prices are being shaded in order to work off stocks.
BLAKE, SCOTT & LEE.

KANSAS CITY, April 6.—Fancy white comb honey continues in good demand at 13½@14c; choice whitest 12½@13c; dark, 10½@11½c. Extracted scarce at 6½c.
PEYCKE BROS.

CLEVELAND, March 9.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.
A. B. WILLIAMS & CO.

BUFFALO, April 21.—Our market is cleaned up on fancy comb; more would bring about 12 cts. There are more or less very poor lots selling at 7@8 cents, at which quite a large amount can be sold. Extra fancy beeswax, 28@30c.
BATTERSON & CO.

OMAHA, April 18.—There is but little stock left in dealers' hands now, and realizing that no further receipts can be expected until another crop gets into the market, it is held firm at 14c for fancy white comb. Extracted, 7½c.
PEYCKE BROS.

MILWAUKEE, March 2.—Fancy 1-lb. sections, 13@14c; A No. 1, 12@12½c; No. 1, 11@12c; dark or amber or old, 7@10c. Extracted in barrels or kegs, white, 7@7½c; dark, 5½@6½c. Beeswax, 25@27c.

Since our last report we have had a very good market for honey, and the demand has been very good for all grades, especially for sections of the best quality, and the demand is good now and small supply. We encourage shipments of best comb. Extracted, fair demand.
A. V. BISHOP & CO.

Nuclei of Bees For Sale.

We have arranged with a bee-keeper in Lee Co., Ill., about 100 miles west of Chicago, to fill orders for 3-frame Nuclei of Italian Bees, with Queens, at \$2.75 each, or in lots of 5 Nuclei, with Queens, at \$2.50 each. Orders can be filled about May 10 and after.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

Order Early

There are indications that the demand for SUPPLIES will be very large this season, and everyone should order as early as possible. We have large facilities for manufacturing all kinds of

No. 18.

Bees and Honey in Utah—Alfalfa.

BY E. S. LOVESY.

THE honey crop here for last season may be considered closed up, and while the figures in the early part of the season were not very high, the demand has been good—in fact, it has been impossible to supply the demand. I do not think there is 500 pounds of comb honey left in the State.

Our State as a honey-producer has been pretty well advertised of late, and consumers and dealers are beginning to find out that Utah alfalfa and white clover honeys are par excellence. Of course, success in obtaining a yield of honey in paying quantities is largely a matter of conditions: it sometimes happens that if one or more bee-keepers by proper management make a success, others think it is an easy way to make money, and they rush so many bees into the neighborhood as to swamp the whole business. By all means this should be avoided. While I might name several instances of the kind here, I will point only to one.

In 1897 one bee-keeper reported a yield of over 300 pounds per colony, spring count; but last season so many bees were brought into the locality that his surplus was reduced to less than 50 pounds, while a number of the new colonies brought in came out in the fall with several pounds less than nothing; that is, there were less bees and honey than they had in the spring.

One thing that some bee-keepers don't seem to realize is, that if their bees are not strong enough to rush forward they often dwindle just as fast backward. But this is not written with any intention to discourage anybody, but rather with a view to advise our bee-keepers to use wisdom in selecting a location for an apiary. If they do this it may prove a benefit to themselves without injuring their fellow bee-keepers.

We had a somewhat peculiar season here the past year. It was short at both ends. In some portions of the State the spring was cold and backward; thus the bees failed to build up as early as usual, but when it did clear up it did so for good, and the flow from alfalfa—our main honey-plant—where there was plenty of irrigation water, was all right; and while some very poor yields were reported, some large yields were also noted, the largest being 10,800 pounds from 31 colonies, spring count, and an increase to 82 colonies. This, of course, is an unusual report, but all in all I believe the bee-industry is in as flourishing a condition as any of the other industries of the State; and if the bee-keepers were only united, and would pull together for their own interest, they would accomplish better results.

We have perhaps one of the best laws in existence for the protection of our bees, and while the law has been en-

forced in many of the counties for the benefit of the industry, still there has been some trouble and considerable loss in a few localities thru a lack of interest on the part of the bee-keepers to get it enforced. But we find that instances of this kind have been an incentive to arouse the bee-keepers to action. It is hoped that our bee-keepers will interest themselves not only in this matter, but also in the purchasing of supplies and in the disposal of their products.

ALFALFA GROWING IN UTAH.

I have received several letters of inquiry in regard to alfalfa, but I do not think that an extended article on it is necessary at this time, as it has been pretty thoroly written up in the American Bee Journal; therefore I would say for

the information of those wishing to try this plant, that it should be sown as early in the spring as possible, so that it may receive the benefit of the spring rains. It is sometimes sown alone here, and sometimes with grain crops; in the latter case I would sow about 23 or 24 pounds of seed to the acre, but if sown alone about 18 or 20 pounds is enough. Where it will produce honey, as a rule, it will be of a superior quality, and while as a rule we regard it as our best honey-plant, in a rainy climate it cannot be relied upon as a honey-plant at all, because, like sweet clover and some other plants, the rain washes the nectar out of the blossoms. But we believe that any place where it will grow it is one of the best forage plants known, and it will produce the most to the acre.

Of all Utah crops, alfalfa (or lucern, as it is called here), we think, is the "boss." Good land will produce about seven tons to the acre, and I know of land where over 200 tons from the acre have been cut since it was first planted, about 30 years ago. Almost any animal that can be named will live and thrive on it, either in its green or dry state, and all stock will eat it in preference to any other hay. I have just been buying a lot of honey-jars packed in clean meadow hay from Illinois, which I tried to save by feeding, but after starving the horses for 36 hours they would not touch it. I then mixt lucern with it, and they pickt out every spear, but left the Illinois grass.

WINTERING BEES IN UTAH.

As a rule, the principal cause of winter loss among the bees in this part of the country is a lack of ventilation. Our bee-keepers, in their anxiety to protect their bees from the cold weather, cover them up and make them so nearly air-tight that it causes the bees to sweat. Then the little air they may have in the hive, when the temperature drops low, becomes foul, which causes the bees to become so weak that they cannot leave the cluster to seek their stores, and thus they hang in the cluster until they starve; when the bee-keeper opens his hives he finds the frames damp and moldy, and his bees dead. I could give over a hundred illustrations to prove this.

Packing is all right if the bees are kept dry. Remember, they must be kept dry. Bees don't often freeze, but they can be easily smothered, and starve. Thus it would be preferable to prop up one end of the cover rather than to seal them down air-tight.

I believe there was four times the amount of snow in Salt Lake county the past winter as in the previous one. Many of the tall pines in the canyons of the Wasatch Mountains were covered out of sight; there were many slides with some fatal results, and while a few of our stockmen felt a little blue, the farmers and bee-keepers felt jubilant, as it insured an abundance of water for irrigation, and a good flow of honey. Salt Lake Co., Utah.

Observations on the Subject of Honey-Dew.

BY WM. M. WHITNEY.

PROF. A. J. COOK, in his article on page 17, under the head of "Honey-Dew—Its Origin and Uses," asks the readers of the American Bee Journal to observe closely this honey-dew, and report the result of their observations.

It has been my habit to observe somewhat closely the production of honey-dew for years, before becoming interested in bees. But I have never known an instance of its production that has not been the result of insect life. I am not sufficiently versed in entomology to be able to definitely classify the different species which produce this kind of honey; but from my observation during last summer, I concluded there were in this vicinity at least two classes or species of aphides at work. To make myself understood clearly, I will be compelled to give a history of my operations in this direction.

The early spring bid fair for a successful season, and on May 13 I put extracting-supers on several hives, and section-cases on others, but soon the conditions changed to such a degree that for some time little was done except to build up strong colonies, which fact I discovered by frequent examinations. This condition continued thru the early white clover and the basswood season, and except for the hope of a supply from sweet clover, our fond anticipations had vanished; but on July 27th, after a respite of ten days, I made another examination, and, to my surprise, I found several of the section-cases partly filled, and quite a number of supers nearly full of honey. The most of it, however, was the vilest looking stuff one ever saw. Lubri-

cating oil used on shafting, until the iron has been ground into it, so as to produce a muddy black, comes the nearest to describing it of anything I can think of, but scarcely any of it was in the brood-chambers, for they were almost wholly occupied with brood.

In searching for the cause, I went into the cherry orchard of 1,000 trees, or more—the nearest point being not more than 20 rods from my bees—and found all thru the orchard, on the under side of the leaves, a black insect, or plant-louse, and the upper side of the leaves was covered with a sticky substance, which the bees were vigorously gathering. This I thought would account for the very dark honey, but there was yet an unsolved problem; there was more light-colored honey than could be accounted for from basswood and clover, for these sources were nearly a total failure. On looking over the lawn of some 30 or more acres, a large number of box-elders were found, on the under side of the leaves of which were found a light green aphid almost transparent, and apparently much larger than those on the cherry-trees, and the upper side seemed to be more completely covered with honey-dew than were the cherry-tree leaves, and the bees were working it as vigorously as I ever saw them on basswood when in full bloom.

Since reading Prof. Cook's article I am more convinced of the source of the light honey than before. The dark honey was all extracted, but what to do with it was the puzzle. But late in the fall the idea of vinegar crossed my dull perceptions, and immediately a warm liquid, that was strong enough to bear up an egg, was made by stirring into warm water honey enough to produce the result. So now I have about 80 gallons of very strong vinegar, which may be increased to 100.

One of the most striking objects to arrest my attention on making the examination for honey-dew was the difference that existed between the honey in two hives standing near each other. Supers were put on both at the same time, but one contained honey-dew almost as black as tar, while the other contained not a cell of such honey, but the contents was as clear and light-colored as any clover honey I ever saw. Query—Do individual colonies of an apiary have fields to which all the bees of the hive direct their attention, instead of scattering promiscuously over the whole territory? This discovery seemed to indicate such as a fact: at least it must have been so in this instance.

Kankakee Co., Ill.

Planting Fruit-Trees and Bushes for Honey.

BY F. A. SNELL.

THE opening of plum-tree bloom follows closely upon that of the cherry, and is rich in both honey and pollen. During fine weather the honey-bees fairly swarm in the trees, proving that a rich harvest is there in store. The air is made fragrant for quite a distance by the sweet perfume floating in the atmosphere. During a profusion of plum bloom no prettier scene can be witnessed than to behold these trees in their snowy whiteness. The bees secure a fine harvest from this bloom to encourage and produce brood-rearing which at this season is so desirable by all apiarists.

Several plum-trees of the different hardy varieties should be grown by every bee-keeper even if the amount of land at hand consists of only a few town lots. Fruit-trees make a good and profitable shade. With the planting of hardy varieties of plums to the number of 25 to 50 trees on every farm, an increase of honey will be secured by our bees, and a profitable crop of fruit secured for family use and to sell. Good cherries as well as plums are in good demand each season and at good prices. If one will give the proper attention I doubt if any crop on the farm will pay as good a return as will an acre or two devoted to cherry and plum culture. The bee-keepers at least should do something in this direction, and may rest assured that a good reward will follow the effort so wisely made.

Apple-trees, peach and pear trees follow in opening of early bloom, or that coming before the small fruits. The apple is here grown to some extent, but not so much as it should be. A good many farmers have bought of unreliable agents, and also trees grown in milder climates than we have, and the trees have often proved not true to name, or tender so they soon die in our colder climate. This has discouraged a good many, and not near the planting has been done that would have been had earlier purchases given good results.

I have great faith in our climate for apples and much other fruit, if hardy, reliable trees are grown or planted.

The planting should consist of trees that have proved hardy in our home or Northern nurseries, buying only of those whom we know to be men of honor. With this rule followed, and good care given, we may grow the delicious apples instead of sending our money to distant States for them and paying freight, and the middlemen their profit besides. Who can estimate the benefit that would result to the bee-keeping industry of our country, and in the better health and wealth of our people?

In the planting of an apple orchard it should be made a point to have a succession of fruit for family use from July 1st to the following April, which is easily secured by the proper selection of a few of each of the varieties to secure the desired end. Four to six trees of each variety will do for an ordinary family.

It must at all times be remembered that bees and fruit go well together, and that while the fruit-bloom is of much value to the bees and their keeper, the bees are also almost indispensable to the fruit-grower, and are his best friends, and aid in securing a good fruit harvest.

Peaches, pears and apricots have been planted here only on a very small scale the past few years, but the first two named have given the past three years good crops, the trees being loaded. Apricots are, so far as I know, too young yet to bear, so it is not known what the result from these trees will be.

Gooseberries, currants, raspberries and blackberries are here grown to some extent, and are of benefit to our bees. The two latter coming in bloom after the fruit-trees are out, help to fill the interim between fruit-tree and clover bloom.

With anything of a favorable spring, with our bees, well wintered, and the planting of fruit-trees and small fruits named above, our hives should be crowded with bees, and some surplus stored when combs are furnished before the close of the fruit-blooming period, and on the opening of clover bloom our bees should be so numerous that each colony would promptly begin work in the supers. As it now is, only a part of our colonies are strong enough to do this at that time, and clover bloom may be in ten days or more before all our bees are storing in the supers.

Fruit-bloom is well known to be an important factor in the securing of a crop of surplus honey. To secure the desired results bee-keepers must do more planting of honey-producing trees and bushes, and encourage others to do so, and they will at the same time reap a double harvest—that of honey and fruit—than which no more healthful products can be named for man's use.

The honey-bees, in visiting blossoms of any kind in search of honey, carry pollen from blossom to blossom, and thus fertilize them and add to the fruit or grain so visited. This fact has been established beyond all doubt. This is of untold benefit to farmers and fruit-growers.

Carroll Co., Ill.

An Explanation of Foul Brood and Its Cure.

BY PROF. A. J. COOK.

I AM asked by one of our intelligent bee-keepers to explain foul brood, and to state whether all microbes are harmful. I am glad to give a brief chapter on these inconspicuous but very significant organisms, from the fact that I have had numerous inquiries of late on this very subject.

Bacteria or microbes, also spoken of frequently as germs, are very minute, so minute that were man magnified as we must magnify these Lilliputian organisms to study them at all, he would appear as large as Mount Washington. They are one-celled plants, and so are of the vegetable world. Some are spherical, others rod-shaped, and still others are spiral. They are classified from these three characteristic forms. The matter of form, however, is not so important really as their physiology or the work they do. As the rod form may merge into the spiral, the microbes reproduce in two ways. They may simply divide—one becoming two or more; or spores, or minute germs may develop, and burst forth and develop into the specific microbes like that which produced them. Not all microbes are harmful. Some are helpful in removing dead matter. We now know that all decay is the result of microbe growth. We see, then, that except for these bacteria of decomposition the earth would soon be clogged by its own dead organisms. Some microbes work on the roots of legumes, like peas, beans, etc., cause tubercles or wart-like excrescences, and in their development breathe in the inert nitrogen of the air and combine it into available form for plant use. They are

thus the cheap, rapid producers of our most valuable or expensive fertilizer—nitrogen, in available form for plant growth.

Other bacteria enter into the development of cream so as to give flavor to butter, and still others add their gifts in the processes of cheese-making so that many of the most valuable cheeses owe their superior excellence either to products arising from the microbes, or to the microbes themselves.

The microbe of foul brood belongs to the rod-like forms, and is one of the forms that develops in living organisms, and breeds decay. Thus these bacilli kill the organism which they attack, and death is followed with decomposition, which is peculiar in color, character and odor. The color is brown, much like that of coffee; the consistency is sticky, stringy, and the thread formed in pulling it out is elastic, so that as it lets go the pinhead which draws it forth from the cell of comb, it flies back. The odor is very penetrating, and has been likened to that of old glue. These microbes seem to work on the tissues, and cause their disorganization. Other bacteria are supposed to generate poisons which tend to destroy the life of their victims. The microbes of diphtheria are of this kind. This is why the substances which are injected to destroy these poisons are termed antitoxins.

The dead larva or brood, victimized by the foul brood bacillus, after decay commences loses all semblance of its former self, and finally dries up and settles to the bottom rear end of the cell a dry scale, but supposed to have the germs of the trouble, so that it will ever be a menace until it is destroyed. As is well known, the cell cap sinks, is often perforated, and the dead brood with these signs in the cappings, the odor, and, best of all, the brown, ropy, elastic matter in the cell, are the best signs that the fatal malady is present.

Every bee-keeper should know these signs, for, unless he does, he may scatter the combs of dead brood, and so spread the disease very rapidly thru his apiary.

The idea of curing foul brood by use of salicylic acid, or phenol, is now entirely given up. These substances were never satisfactory, as they were very uncertain. Many careful apiarists secured no good at all by their use. To put the bees in a new hive on foundation, let them remain four or five days, gathering from the field or being fed as circumstances demand, then melting up these as well as the other combs, after extracting the honey, and living again on foundation, we entirely eradicate the disease. We have destroyed all the germs. The one danger is in scattering the honey as we manipulate the bees and combs. We must know that this honey has the germs of death in it, and so must be most cautious not to give any chance that any bees can ever get any of it until it is scalded. We must scald out the extractor after use.

Mr. McEvoy, of Ontario, says there is no danger of using the hive again, with no pains to scald it out. As he has had a very wide experience, treating thousands of colonies, he is certainly good authority.

Los Angeles Co., Calif.

One-Piece vs. Nailed Sections—A Foul Brood Inspector's Experience.

BY F. BOOMHOWER.

ON page 154, in "Beedom Boiled Down," it is reported that Mr. Doolittle says in the Progressive Bee-Keeper that he considers the nailed sections the best, as they will stand shipping better, and are not so apt to break down.

Now, I have never known any section, whether nailed or otherwise, to break down in a shipment. I have in the last 20 years handled and shipped upwards of 75 tons of comb honey, both by rail and water, and some by rail that went long distances, and I have never yet had a box to break, neither have I had a shipping-case to break, and I make the cases very light at that. Our cases hold 24 sections, and are made of basswood, weighing only 2½ pounds. I think it a waste of lumber and a useless expense to make boxes and crates of such heavy material. The ends of our cases are scant ½ inch thick, and generally the bottom and top are 3 16.

To nail sections is like going back to the old scythe and snath to cut grass. I would like to see Mr. Doolittle sit down with a job of 30,000 or 40,000 sections to nail. A dovetailed section can be put together before Doolittle or any one else can pick up and drive one nail. And if the dovetailed joint is glued—which we always do—a dovetailed sec-

tion is stronger, and will stand more banging than any nailed section I ever saw, and I used to nail a good many. I have seen a case of honey drop over 10 feet to the ground, with dovetailed sections, but not a box was broken: of course the honey was masht.

A LAUGHABLE EXPERIENCE IN FOUL BROOD INSPECTION.

I would like to relate a laughable experience that I had last fall while I was inspecting bees for foul brood.

I was notified one day to examine some bees about 10 miles from home. After some inquiries, and traveling over a very crooked road, opening at least a half-dozen pairs of bars, I found the place, and walkt up to the door. I rapt gently, and a large, portly woman with sandy hair and an extremely large mouth responded to my rap. I lifted my hat, and in as gentlemanly a way as possible bade her good afternoon. I askt her if her husband, Mr. H., was at home. Drawing her mouth to one side, the corner of which extended nearly to her left ear, and cocking her head to one side as far as her shoulder would permit, she replied:

"Y-e-s, he is over on the hill raking up buckwheat, a half mile or more away. *What dew yew want to see my husband for?* At this outburst, and the important way with which she brought it out, I made up my mind I had struck a snag, and it would be policy for me to proceed very carefully, for I had had some experience before, and something seemed to whisper in my ear, "Look out, old fellow, there is trouble ahead."

I smilingly and very genteelly replied that I had been informed that they had some bees that were diseased with foul brood, and that I had—but before I could finish my answer she strode up to within about two feet of me, and again cocking her head to one side, and putting both hands upon her hips, extending her mouth this time until the corner was so far around as to be invisible, she said:

"*A-r-r-y-e-w* the chap what's around burning up foaxes-b-e-e-s?"

Cautiously and carefully taking a step or two backward, and slyly glancing my eye over my shoulder to measure the distance to where my horse stood, in case of emergency, I replied that I had come to examine their bees, and if they were badly diseased, and no hope of saving them, I was there to see that they were properly taken care of. Again she came up toward me, and lifting that long arm with indignation and scorn written on her face, with her front finger she pointed towards the lane whence I had come, and roared out:

"No-o-y-e-w g-e-e-t! If you don't I'll scald your eyes with hot water!" At this she made a dive for the kitchen, but as good luck would have it the fire was out, and I could hear her upbraiding one of her girls for being so shiftless as to let the fire go out, and not a drop of hot water in the teakettle.

"Oh," she said, "if I only had some hot water," coming back again to where I stood. Oh, I shall never forget the look that creature gave me, as then she bolted around the house out of sight, and at once began yelling to her husband to come to the house quick, for the man was there to burn up the bees. Oh, what a pair of lungs that woman did have. I thought to myself, when I heard that voice, if every one had such lungs we would not have any use for short-distance telephones. She made the hills and valleys ring, and as it echoed back and forth it reminded me of the old, long tin-horn that my grandmother use to blow to call the men together in anti-rent times, when the sheriff was coming. If all women had such a voice the tin peddlers would have no traffic in dinner-horns. I thought about A. I. Root, where he tells of getting his second wind while riding his wheel; if he only had half of the wind that woman had, he would not have to wait until he got his second wind.

After giving vent to those lungs, she rusht back to where I was standing, and if ever a man got a dressing down it was myself. Vainly I tried to reason and explain to the woman, but it was of no avail—her tongue was loose at both ends and hung on a double swivel with ball-bearings, well oiled, and it would have to be an expert at short-hand to have kept track with one-half of what she said.

Finally her husband appeared around the corner, and after introducing myself and explaining to him the object of my visit the best I could under the circumstances, we proceeded to examine the bees, after he had partly quieted her down and told her to shut up, and not to make a fool of herself.

I got a hive open, and to my great joy I found that they were about the crossiest bees I had ever come in contact with, as she stood there with an old mop-stick, flourishing it at me. I had fully made up my mind if she made a charge

at me I would arouse the bees in my defense, and drive her from the field. I bumpst the hive and shook the bees, and even crusht a few so as to arouse their ire. It was but a moment before I was master of the field. Her husband made a dive and shot into an old pigpen with a lot of fighting bees in hot pursuit; and, glancing over my shoulder, I saw a sight I never shall forget, and often in my sleep I have dreamed about it, upon awakening I have laughed out loud, and my dear wife has often told me that she believed I had the nightmare, but it was no such thing. It was only a vision of a 200-pound, red-haired, sandy-complexioned woman, with powerful lungs, a calico apron over her head, stamping and jumping with a few bees twisted up in her golden locks, with a mop in one hand, trying to get thru an old woodhouse, and calling to her daughter to come and pull a stinger out of her nose.

I proceeded to examine the rest of the bees in peace, and when once in awhile I would quickly glance up toward the house I could see the old woman peeking out of one window, and the husband and a couple of red-headed girls looking out of the other.

I found the bees rotten with foul brood, and rotten-broody combs strewn around the yard from colonies that had succumbed to the disease long before.

Finally, before I left, the husband came out, and then I told him that he seemed to be a quiet sort of a man, with considerable sense, and that I did not believe there was a law in New York State that would compel a man to live with such a woman as he had. He replied that he had become used to it, and one must not pay attention to all that women said.

Schoharie Co., N. Y.

Is Pollen Fed to Larval Bees?—If so, in What Form?

BY G. M. DOOLITTLE.

A LETTER lies before me in which I find the following: "Do larval bees, at any stage of their existence as larvæ, eat pollen, or is their food of some other material? I see it is claimed by some that the young bee in the larval state does not eat pollen, but its food consists of a purely animal secretion. Please tell us thru the columns of the American Bee Journal what you think regarding this."

I am not informed in these matters to an extent sufficient to be considered an authority on this subject, therefore I am very glad to know that my "think" is what is wanted of me, rather than what I *know*. However, I am glad this question has been brought up, for it will be one of interest to most of us, and it will be a good time during the summer months to interrogate the nurse-bees, and perhaps while they are liberally feeding the larvæ they will tell us just what it is they are feeding them.

From many careful observations during the past, regarding the food of larval bees, I have been led to believe that such food is composed of about two parts honey or saccharine matter, four parts pollen or flour (where the latter is used in early spring as a substitute for the former), and one part water, the whole being taken into the stomach of the nurse-bee and formed into chyme, after which it is given to the larval bees in the cream-like form we see it surrounding the larvæ in the cells.

Right here I wish to digress a little and give some other observations as bearing on the eating of pollen by the old or hatch bees. The older readers of the American Bee Journal will remember that some ten or more years ago I told how I starved some colonies entirely, and others partially so, trying to make them eat pollen in the fall, and at other times when there was no brood in the hive: and that, so far as I could see, not a cell of pollen was toucht. At another time some of the colonies had to be fed, when I again tried an experiment which I had formerly tried several times, which was to see if the bees, in hives which had scarcely a cell of honey in them, but plenty of brood in all stages, would live, if provided with pollen.

As the weather at the time of this latter experiment was so bad that the bees did not fly for several days, it was with much anxiety that I waited to see what would be the outcome of the matter after the honey was gone. The first thing noted was that, as soon as the few cells of honey were gone, the larvæ was scrimpst for food, and the eggs removed from the cells, or more probably eaten by the bees, while a little later there was a general eating of the larvæ. A day or two later the sealed brood was taken from the cells and suckt dry, while the harder parts were scattered about the entrance and bottom-board of the hive. At this time I no-

ticed the bees putting their tongues together as they do when bees feed the queen, this thing being continued till nearly all the pollen was used up, which lasted for several days, when it came good weather again, so new supplies were gathered.

From these observations I formed the opinion that old bees partake of pollen only in the form of chyme, and that this chyme is prepared only when there is, or has been, brood lately in the hive. I have thus wandered to show that pollen can become a factor in our problem of wintering of bees, *only in connection with brood-rearing*, and that, where no brood-rearing is carried on, pollen can have nothing to do with the so-called disease—bee-diarrhea; and the result of the past winter, during which many colonies have had the diarrhea, only add strength to former opinions. But to return.

That the larval bee subsists wholly on this chyme, or creamy food, I think no one will deny; and if from my observations I am correct, the largest element in this food is pollen. As the larva absorbs this food the grosser part of the pollen forms itself into the yellow streak seen in the larva when taken out of the comb, but most plainly in the drone-larva, which streak is finally enclosed by the intestines of the newly-hatched bee, and evacuated on its first flight.

If I had time it might be interesting to digress here again, and tell how I have found, by experimenting, that newly-hatched bees which have not had a cleansing flight are practically worthless to ship with queens long distances, and that I always avoid, as far as may be, catching such bees when sending queens to Australia and other distant countries, because they are liable to daub the queen and cages with their excrement, or die from over-distended abdomens; but I will not take the time here. To show that I am not alone in the belief that larval bees eat pollen, I wish to give the testimony of others who incline to a like belief:

A. I. Root says: "It is supposed that this larval food is pollen and honey, partially digested by the 'nursing bees.' Bees of this age, or a little older, supply the royal jelly for the queen-cells, which is the same, I think, as the food given to very small larvæ. Just before the larvæ of the worker bees and drones are sealed up, they are fed on a coarser and less perfectly digested mixture of honey and pollen."

Prof. Cook says: "The food is composed of pollen, for, as I have repeatedly proved, without pollen no brood will be reared."

Quiuby says: "How this food is prepared is mere conjecture. The supposition is, that it is chiefly composed of pollen; this is strongly indicated by the quantity which accumulates in colonies that lose their queens and rear no brood."

Gallup says: "Every bee-keeper ought to know that bees do not feed pollen directly to their young, but it is elaborated in the stomach of the bee into chyme to feed the young on."

Kirby says: "With this pollen, after it has undergone a conversion into a sort of whitish jelly by being received into the bees stomach where it is probably mixt with honey and regurgitated, the young brood, immediately upon their exclusion, and until their change into nymphs, are diligently fed by other bees, which anxiously attend upon them, and several times a day afford a fresh supply."

Neighbour says: "A portion of this pollen is taken at once by the nursing bees, which are supposed to subject it to some change before offering it to the larvæ."

Gundelach says: "The larvæ are immediately fed by the worker-bees, with a pellucid jelly prepared in their 'chyle stomachs' by the digestion of honey and pollen mixt with water."

In the above I have told what I think in the matter, and given the "think" of several others, who very nearly, if not quite, agree with me; and I should be very much pleased to hear from any who do not agree. Let us all try to see if we cannot arrive as nearly at the truth in this matter as possible during the coming season's work with the bees.
Onondaga Co., N. Y.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

CONVENTION PROCEEDINGS

Report of Wisconsin Bee-Keepers' Convention.

The 15th annual meeting of the Wisconsin State Bee-Keepers' Association was called to order by Pres. F. Wilcox, Feb. 9, 1899, in the Lieutenant Governor's office at Madison.

The secretary's and treasurer's reports were read and approved.

H. Lathrop, as committee to secure freight rates on bees in less than car-lots, reported that after several efforts no rates could be secured. Mr. Johnson spoke of taking a sample hive to the general express office in Chicago, and getting a special rate to ship bees by express as cheap as by freight.

The members then listened to a paper by John Trimberger, of Clark Co., on

What to Do with Unfinished Sections.

By way of introduction, and to emphasize what comes after, I will say that I have been in the bee-business 20 years. For five years I kept bees for pleasure and experimental purposes in all kinds of hives then known. In 1884 I had the good fortune to change to the 8-frame Grimm-Langstroth hive and the Heddon super; and have in use nothing else to-day except three of the New Champion chaff-hives. Last and most important I have used nothing but the 7-to-the-foot open-top section.

Your worthy secretary struck me right when he wanted a short paper on the above topic by a practical bee-keeper. I accepted because I hold myself to be immensely practical. For instance, I have never been fooled with reversible frames. Neither did I ever fool with no-bee-entrance or plain or tall sections, or fence-separators; nor have I been fool enough to break up or smash unfinished sections.

There was a time when bee-keepers almost unanimously advised to save unfinished sections for next year's crop, as they were worth their weight in gold. That was good. Then came a time, and it is on yet, when too many bee-keepers advocated and still hold to the absurdity of extracting the honey from unfinished sections; cut out the comb and break up the section lest you should be tempted to use them next season and spoil the whole comb-honey business. That was and is very bad! Only the loquacious paid writer or the manufacturers of sections and comb foundation could advise such a detrimental course.

You are already aware that I do not hold drawn or partially-drawn comb responsible for the occasional appearance of sour or watery comb honey. I will presently endeavor to show how and when such are apt to occur. Let us create an occasion and a condition. Here is a strong colony of bees June 24, with one surplus super on. Honey is coming in fast. We go thru the bee-yard to see where surplus room is needed. We come to this colony and notice with regret that we are a week late. The super was put on with an inch starter of extra thin comb foundation. Now it is full of comb honey, one-fourth of which is capped—finished—ready to take off. We are prest with work. The super is lifted and an empty one added underneath. Next day this colony swarms, and it swarms again and again; but the hive is left standing undisturbed until we come around again on July 24. Ten to one, the honey is watery. It has an ashen-gray, bluish lead color with death perspiration standing in relief. For the same reason such comb honey will hardly ever be found after the swarming season is over and the bees have permanently settled. Such honey is put on the strongest and liveliest colony in the yard, or carried into the honey-room and set two or more feet above the floor, where a temperature of 90 degrees, Fahr., is maintained, artificially if necessary, and by letting the sunshine in full blast whenever it wants to. In a week or two it will be fair honey in the comb. I know of instances when it was reclaimed or resuscitated to represent fancy white comb honey.

We handle sections by the super or case. When the first super is filled, or nearly so, it is taken off, the unfinished sections taken out, and after being leveled with the uncapping knife, if any be bulging, returned to the colonies for completion.

In the fall, when the grand conglomerate sweepstakes of surplus is carried into the honey-room, the orthodox temperature as above must be maintained. The finish sections are placed six in a compartment of the super where formerly had been seven, making 24 to the super. Commencing well up from the floor, these are tiered with a piece of lath between every other one to give free circulation of air. The unfinished sections are assorted and piled up the same way. Those that are well filled and capt one-half and better, to the point from which they go as finish combs, are packed in regular shipping-cases, to-wit: Three sections long, six wide, two tiers high, 36 sections in all, and sold cheap at 8 cents a pound close at home. Two cases pay our road tax; one is given gratis to this neighbor, one to the other. The minister gets one free of charge, sure. All go like hot-cakes.

For two seasons I have used the Taylor handy (so-called) comb-leveler. To use it the honey must be extracted and the combs licked clean by the bees. Light your lamp. Put water in the trough around the melter. Wait half an hour till all is hot enough to start in. Place your comb on the leveler and wig-wag it. When melted down to the prescribed limit, lift off. With a case-knife scrape off propolis and wax quickly lest it might ignite. With a tiny penknife open the sealed air, as air can be readily artificially sealed in this manner. I have purposely and repeatedly left such sealed air-cells untouched, and put on the hives the following season when the bees left them the same; and I might have done a splendid business had air more weight. Beware lest a despairing sigh escape you; blow the moat dry, extinguish your lamp, etc., only to start fresh again.

All this is obsolete with me now. I do it no more. My first step in fixing the remainder of the unfinished comb is by taking three unfinished sections and the Bingham uncapping knife to the near-by village barber who hones it (the knife) to a razor edge. I now resolutely walk into the honey-room with the devout determination of doing a good chop. The aforesaid temperature is somewhat lowered to be more comfortable. A frame made of lath, unplanned and unpolished (because it so holds the sections better) is laid on the table. It holds six sections. The left hand picks up a section, and with the aforesaid knife is made one great cutting sweep to the left and one to the right and one side is uncapt and the comb cut down low so that when the other side has received a similar treatment it is about an inch thick. Sections go into the frame, the frames into the extractor, the honey into my ripening and clarifying tank. Here is where the 7-to-the-foot open-top section scores a big point. You can cut the comb down easily.

All the unfinished sections, whether or not they contain honey, are leveled. The tops of the cells that are propolized, even when low enough already, are shaved off. Propolized foundation is cut out entirely. The honey being all extracted from the sections, they are set out for the bees to lick clean and dry, so they can be stored away until the next season sees them on the hives again, to be filled by the bees and capt snow-white, to be shipped to market as fancy white comb honey. JOHN TRIMBERGER.

A lengthy discussion followed, especially upon evaporating honey not ripened as it comes from the unfinished sections, and at times in extracting.

QUES.—Is all unsealed honey unripe honey?

Several replied no, especially that gathered in very dry weather, and often the fall-gathered also; that each bee-keeper should know at sight any honey that is ripened, and never take from the hive before such quality is secured.

A recess was taken to pay the annual dues, which was responded to by a large number, representing 14 counties in Wisconsin in attendance, and delegates from two other States.

Next was a paper by H. Lathrop, on

Producing Comb Honey Without Increase.

If your bee-cellar is not sweet, sprinkle a good coat of fresh lime on the floor. If the trouble is simply dampness, six or eight inches of dry oats-straw scattered on the floor will do much toward helping the matter. I have a bee-cellar that has a very moist, porous bottom; by using the straw as described, it has wintered very successfully for a number of years.

A certain bee-keeper has a chance to rent 35 colonies of bees from a farmer for next season. He wishes to run them for comb honey and take no increase; he will keep them where they now are on the owner's premises and bargain to leave the original number at the close of the season. How can he manage? There are several ways of procedure

in such cases; I will mention two, either of which will work. I should visit the apiary in the spring often enough to see that each colony, if possible, was gotten in shape for the honey harvest, by feeding any that needed it, by equalizing and by seeing that each colony was provided with a queen that could attend to her proper duties.

Now when the honey harvest begins, provide all with supers that are in shape to work in them. Very likely some of the colonies will not swarm at all if given surplus room at the proper time, but you will have some one on the ground often enough to attend to the swarming question in the way that I shall point out. When you find a colony preparing to swarm by having queen-cells well under way, take a sharp knife and cut out and remove about two-thirds of the brood, including all that has queen-cells started on it. The bees will go to work and build down the combs again, and swarming will be stopt, very likely, for the season, especially if they are well at work in the sections. The brood thus removed can be placed over weak colonies, if there are any, in almost any kind of box, and allowed to hatch and build up the colony, or you can take it home and feed it to the chickens, and put what they leave into the wax-kettle, so that nothing will be wasted. In this way you may take a good crop of honey and have no increase of colonies.

This may look like a rough and wasteful way, but it answers the question, and it will work. At the close of the season the bees are all right, and have their combs rebuilt, so what harm has been done by cutting out the brood? Of course such work is not recommended for novices—it requires one who has a practical knowledge of bee-keeping; but even if practiced by a novice it would often result in far better returns for the labor expended than what is gained by the old method of letting the bees swarm and swarm, furnishing hives to put the new swarms in, the result—a lot of weak colonies to die during the winter or coming spring, and no surplus honey, unless the season happens to be an extraordinarily good one.

The other plan, which I will briefly outline, requires more fixtures, but as I said of the first, it will work if properly carried out. Make some cheap shallow cases of common fencing, same width and length as the hive, put sticks in the top to correspond with the top-bars of the brood-frames. When a colony swarms remove the hive to one side with the entrance turned in the opposite direction; hive the swarm in the shallow case on the old stand; reduce the old hive as much as possible, by getting all field-bees into the temporary brood-chamber.

After a few days when they have gotten well started in building combs, you can give them the supers that were on the present hive, or you can do so at once by using a queen-excluding honey-board.

After the first day turn the old hive around and allow it to remain beside the other with the entrance the same way. On or before the seventh day you can weaken the old colony to prevent further swarming, by shaking off the young hatching bees from the combs and letting them run into the other, which is to be made the working colony. The temporary brood-chamber being small, the queen will occupy nearly the whole space with brood so that you will get nearly all the surplus honey in the sections. After the honey season has closed, all supers have been removed, and you wish to leave the original colonies as you found them, place the old hive back on the original stand, and on top of it place the temporary brood-chamber; leave it there until brood-rearing ceases, and all brood is hatched, then place a bee-escape under it, and when clear of bees take it away. It will be seen that when these two colonies are placed the one on top of the other, that there is a queen in each; one can be removed by the bee-keeper if he desires, otherwise the bees will do it. Almost any bee-keeper will know what to do with these shallow cases containing strips of comb and a very little honey. They can be saved entirely for the same purpose another year, or the honey and wax can be gotten out of them by the agency of heat.

Now, if any of my bee-keeping readers think they can furnish a better answer to the original question than the foregoing, I would be glad to have them do so, as I am here to learn as well as to furnish what information I can relative to the subject of bee-keeping. H. LATHROP.

As Aug. Weiss was present, and making over 14,000 pounds per year of his comb foundation, and having samples of foundation and long rolls of sheeted wax with him, many questions on comb foundation were answered by him.

(Continued next week.)

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

No Bee-Supplies for Sale.

Could you spare me a couple of queens now? If so, what kind are they, and what is your price? WISCONSIN.

ANSWER.—I don't keep anything in the line of bee-supplies for sale.

Albino Bees—Danzon Baker Hives.

1. Will albino bees give as good results as Italians?

2. Is the Danzon Baker hive a good one for the beginner? CONNECTICUT.

ANSWERS.—1. Some albinos are better than some Italians, and some Italians are better than some albinos. Taken all in all, bee-keepers who work for honey seem to prefer Italians.

2. Depends something on the tastes of the beginner. For the majority it is perhaps not the best.

Bees Affected with Paralysis.

I have two or three colonies affected with paralysis, and can find but little advice in my books. What do you think of moving affected colonies, as fast as discovered, to some place away from the apiary? How far do you think it necessary to move them? ALABAMA.

ANSWER.—I don't believe it would do any good. If the disease can be conveyed by having affected bees enter sound colonies, there would be no surer way to spread it than to move away the diseased colonies, for that would make the field-bees of the affected colonies enter the sound ones.

Colonies Deserting their Hives.

My bees swarm out and go into other hives, queen and all. I had 35 colonies, and eight of them came out and went with others. They did not rob, nor did they fight. I never saw this before. Some were good colonies. Can you give me any insight into this trouble? MICHIGAN.

ANSWER.—The trouble you mention is not so very rare, but it is not an easy thing to say why a colony with clean combs, having plenty of brood and honey, deserts its hive for another. I've some times thought it was because the old bees had died off rapidly, leaving more brood in the hive than the bees could cover; but as a matter of fact, I don't know.

Foul Brood—Good Text-Books.

1. I am a young bee-keeper, tho an old man, and ready to acknowledge my ignorance about the business. One of the things I don't know is, what "foul brood" is. Will you kindly describe it so that a novice can detect it?

2. I would like some good work on bee-culture. Will you please indicate some work suitable for a novice in the business? MICHIGAN.

ANSWERS.—1. Turn to page 161 of this Journal, and you will find an admirable reply from Hon. R. L. Taylor—"Foul Brood in a Nutshell." [Also on page 275 of this number you will find Prof. Cook tells something about it.—EDITOR.]

Root's "ABC of Bee-Culture," Dadant's "Revised Langstroth," and Cook's "Manual of the Apiary," are good text-books on bee-keeping.

Using Hives and Combs Left by Dead Colonies.

1. During the severe cold weather last winter, four of my colonies of bees on the summer stands died. My plan is to put their hives under some of my strong colonies, then about swarming-time move the top hive to a new stand, and leave the bottom one on the old stand, and introduce a queen in the queenless hives. Will my plan work?

2. When will be the best time to put them under?

3. There is considerable honey in the hives of the colonies lost. Would you advise feeding after I put them under, or just let them

alone? My wish is to have as many good, strong colonies as I can by the time the honey-flow begins.

I wish to thank you for the answer to my last letter. Just as soon as I received the American Bee Journal and found your answer, it being a warm day, I went out and turned the hive upon the bottom-board, and began to rake out between the frames. The first thing I saw was Mr. Mouse running out. Then I saw the tail of a mouse on the bottom-bar of one of the frames. I pulled him out; he was dead, and so large that I had a hard time getting him out. I will look out for mice after this.

4. Will it be well for me to close the entrance of my hives some during cold days? I am using 8-frame dovetailed hives. ILL.

ANSWERS.—1. It may work all right, and it may not. Depends somewhat upon whether the colony is strong enough to work down into the lower story.

2. No matter how soon. It will do no harm to put them there right away, and will be the better for the combs.

3. With plenty of honey it isn't necessary to feed.

4. It would be a good deal of trouble to change the entrance daily to suit the weather, but it may be well to contract the entrance till warm weather comes.

Colony Destroying Eggs.

There is one of the most peculiar freaks now being indulged in by one colony of my bees, and I can't unravel the cause for such action. The bees destroy all the eggs transferred with combs from other colonies. It is quite strouged with bees, and one of my best colonies of 1898, having a clipt queen, but commenced breeding quite early this season, and all hatch drone-bees, becoming a drone-layer. I have taken at different times frames from other colonies and inserted in the hive; the bees immediately destroy all eggs and even clean out the cells where hatched. I confess that I am unable to solve the mystery. OHIO.

ANSWER.—I don't know. I have noticed that it is a frequent thing when a colony becomes queenless, or when a frame of eggs is given to a queenless colony, for most of the eggs to be removed or eaten, but I don't know why. It has also been said that when breeding ceases in the fall, it is the work of the workers rather than the queen, for there is a cessation of hatching some time before the queen stops laying.

Division-Boards—T Supers, Etc.

1. Is a common, 8-frame dovetail hive, 12 $\frac{1}{2}$ inches wide, suitable for eight frames without a division-board? or would it space them too far apart? Do not a good many use them without division-boards?

2. Is it necessary to use any support for medium brood foundation in frames like yours, where it is firmly fastened at both top and bottom-bars?

3. In using T tins in the super, do you fill out at the ends with dummies? MISSOURI.

ANSWERS.—1. Probably not many use dovetail hives without division-boards, for most of them have self-spacing frames, and it's rather necessary to have a division-board—more properly a dummy—to get out the first frame. But eight loose-hanging frames will work all right, the only difference being that the frames will be spaced 1 $\frac{1}{2}$ inches from center to center, a distance that some good authorities approve. But I would hardly advise loose-hanging frames.

2. Fastening at top and bottom will not do, for the foundation would stretch and bulge badly.

3. No, the T supers are shorter than the hives, and don't need anything to fill out the ends.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

MAY 4, 1899.

NO. 18.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

See that All Colonies Have Stores is the advice given in the Progressive Bee-Keeper by G. M. Doolittle, who prefers for that purpose combs of sealed honey, and next to that combs filled with feed, in either case these combs placed in the center of the brood-nest to stimulate the queen to greater laying.

Increasing the Association's Membership.—Mr. Herman F. Moore, secretary of the Chicago Bee-Keepers' Association, sends us the following suggestions looking toward an increase in the membership of the United States Bee-Keepers' Association:

MR. GEORGE W. YORK, Editor American Bee Journal.

Dear Sir: I have a suggestion to make in regard to the United States Bee-Keepers' Association. Is there any reason why every bee-keepers' association in America should not be affiliated with the national organization? Why can't we say to the Philadelphia association, "Join us as a body, and your first year's dues will be only 50 cents a member?"

In the first place, we would get the addresses of all the bee-keepers who are members of any bee-keepers' organization, and interest them specifically in our work. In the second place, we should no doubt largely add to our membership list, for it is quite an inducement to get in for half-price. The local associations could vote the money out of the treasury, and levy a tax on their members to pay it.

There might be an association membership fee of \$5.00 or \$10 a year. Of course, certain benefits should be conferred for the consideration of such membership. An asso-

ciation should be entitled to one delegate to the annual meeting of the United States Bee-Keepers' Association for each 10 or 25 members of the local affiliated association.

A prize of \$10 might be given to the local association sending in the largest list of new members.

It seems as if considerable advance might be made along the line mentioned, and perhaps more elaborated. I hope this will be taken up and discussed generally by bee-keepers in the various journals.

As to the proposed union of the two big associations, let some one hunt up the names and addresses of all those who are members of both (and I suppose favor amalgamation), and let them correspond with each other regularly until the desired result is brought about.

HERMAN F. MOORE.

Some years ago an effort was made to get local bee-keepers' organizations to affiliate with the National, but only a very few of them seemed to think enough of the matter to thus become affiliated. But perhaps circumstances are different now, and something might be accomplished along the lines indicated by Mr. Moore.

We would further suggest that Mr. Moore's ideas be considered at the Philadelphia convention, next September, as no definite action can be taken before that time. It might be well, however, to discuss the subject in advance of the meeting, so that various opinions might be thoroughly understood and be given due attention when the time comes for final decision.

Cuban Bee-Keeping is not very encouragingly spoken of by "An American Tramp" in Gleanings. He says the wages paid to bee-keepers are from \$15 to \$25 per month and board. The houses in the country have been burned down, and those in town are so filthy that no woman from a comfortable home in this country would be content to live in them. Fleas are so bad that he says he had to wash himself with kerosene oil to get any rest, said oil costing 50 cents to \$1.00 a gallon. Whisky and cigars are cheap, other necessities (?) high.

We are inclined to agree with Editor Root in his views as expressed in the following comment on the article by "An American Tramp":

"I have concluded not to go to Cuba just yet. If I must bathe myself in coal-oil at \$1.00 per gallon to keep off fleas I'll stay at home awhile longer. Seriously, one should think twice before going to this land devastated by the hand of war. Conditions will improve, no doubt, in the near future. In the meantime the average bee-keeper better keep his good dollars and invest them at home."

The American Bee-Keeper for April contains this editorial paragraph:

"From a recent letter written by Mr. Craycraft, of Cuba, the following interesting notes were gleaned: There are six or eight apiaries of importance in the vicinity of Havana, aggregating perhaps 1,600 to 1,800 colonies. There is still some foul brood in that locality. The apiary formerly owned by Mr. Osburn is now in the hands of a Cuban. A Mr. Rayelo, having about 400 colonies eight miles south of Havana, had, on Feb. 10, taken something over 3,000 gallons of honey this season. It is Mr. Craycraft's opinion that Cuba produces the finest grade of honey in the world, and that some enterprising person or firm is needed to bring it before the world. Mr. Craycraft takes a very cheerful view of Cuba's apicultural future."

Spraying Fruit-Trees in Bloom. It is very encouraging to see that fruit-men are beginning to understand more fully that bees are their friends, and to deprecate the practice of spraying fruit-trees when in bloom. The following appears in the National Stockman and Farmer, not in the apicultural but in the horticultural department:

A correspondent in Franklin, Pa., writes: "I think it is unlawful to spray fruit-trees while they are in bloom with poisonous mixtures of paris green, etc., and it would be well to call attention to the matter in your valuable paper. Some

farmers spray when the trees are in bloom, and thus destroy many bees, which is certainly wrong."

REMARKS:—There is probably no law on the subject in some of the States, and yet there should be. No thoughtful person, even tho he has no bees of his own, would be willing to injure those of his neighbors: but some people are not as careful as they should be.

The time to spray is, first, before the buds expand, and, second, after the bloom has fallen off. Subsequent sprayings may be necessary, according to the judgment of the orchardist, but there is no need to spray while the trees are in blossom. The bees are among the best friends of the fruit-grower, carrying pollen from one flower to another, and from one tree to another, and any one who raises fruit—of any kind—will find it to his advantage to keep bees, even without taking the honey into account.

It would be a splendid thing for both fruit-grower and bee-keeper if all the farm papers would stand with the able National Stockman and Farmer in this matter. Of course it takes time to educate the public, but it can be done if persisted in by those who know the facts and can spread them among the people.

Advertising Bees and Queens.—Owing to the quite severe and general loss of bees the past winter, there will likely be a good demand for bees and queens. In view of this, we would suggest that those who will have any for sale cannot do a better thing than to offer them thru an advertisement in the American Bee Journal. Our rates are very low, considering the quality and quantity of our weekly circulation. Send for rates on advertising if you are interested in the suggestion we have made.

Also, all dealers in bee-keepers' supplies will find it to their interest to keep their advertisements standing in our columns. The G. B. Lewis Co. now are using a half-page of space; the A. I. Root Co. a third of a page; and many others who do any business realize that if they want to reach bee-keepers they must use space in a paper that goes to the people they want to induce to become their regular customers. Those dealers who have tried it say that the old American Bee Journal draws business their way. It would be glad to help turn some your way, too, if you want it to do so, and if you are not already among its list of reliable advertisers, and deserve to be found there.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 50 cents; 50 for 70 cents; 100 for \$1.25; 250 for \$2.75; 500 for \$4.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

EDITOR HILL, of the American Bee-Keeper, says: "Why not begin the season right by adopting some good record system? One year's experience will convince those who have not tried it, of its advantages."

THE DREXEL POULTRY-YARDS advertised on page 283 of this issue, are owned by a personal friend of the Editor of the American Bee Journal. He will give entire satisfaction to all who extend to him their patronage. If you are interested, give him a trial order, not forgetting to mention having seen the advertisement in the Bee Journal.

A LANGSTROTH MONUMENT SUGGESTION comes from the Island of Jamaica, as follows:

"Mr. Secor, on page 200, asks for approval or otherwise of the inscription for Father Langstroth's memorial. Having subscribed our mite, allow us to suggest that the wording remain as it is, only arrange it so that it will represent a Langstroth frame; or have the words engraved on a Langstroth frame in relief. In some way the *movable frame* should be shown, and not *less than \$500* spent on the shaft.—JAMAICA."

GENERAL MANAGER THOMAS G. NEWMAN, of the National Bee-Keepers' Union, writing us April 24, said:

EDITOR AMERICAN BEE JOURNAL:—On page 248, it is stated that I have made "demands" as a condition of amalgamation of the two Unions, and that these are never likely to be assented to by General Manager Secor, and that there the matter rests, etc. This is *news* to me. I have never made *any* "demands" in that line, and *call for the proof*.

Yours truly, THOMAS G. NEWMAN,
General Manager.

We think perhaps Mr. Newman has taken Mr. Abbott's words, as given on page 248, a little too seriously. We do not know to what he (Mr. A.) referred, but are certain that whatever it was, it must have been only a mere difference of opinion, and likely the word "demand" was not the proper one to use, as we do not know that Mr. Newman has *demand*ed anything lately in regard to amalgamation. Still, we haven't much doubt that before a uniting of forces could be consummated he would require certain conditions ere he would advise the Union to go in with the Association. But we don't believe any further public discussion of this matter is either necessary or desirable.

MR. FRANK BOOMHOWER, of Schoharie Co., N. Y., is suggested as State inspector of apiaries by Mr. P. W. Stahlman, of that county, in the following, dated April 22:

EDITOR YORK:—I notice on page 248, that the proposed Foul Brood Bill has become a law in New York, and I endorse the words that Mr. H. S. Howe expresses, viz.: That its success will depend upon the man who may be appointed inspector. I think that Mr. Frank Boomhower, of Schoharie County, would be the man for the position. He has been inspector for two years in his county, and has done good work. (See his article in Gleanings of Sept. 15, 1898, page 691.) He is a man of 26 years' experience in the bee-business and has had much experience with foul brood. He attends strictly to his duties, and is very particular in all his work about bees. He knows what he is doing, and has the "git" to push things right thru. I know of no better man in New York for the place. P. W. STAHLMAN.

On another page of this number will be found an article by Mr. Boomhower, in which he gives a sample of the experiences he has in his work as inspector. In the case cited he evidently exhibited great bravery; and if he can handle the disease known as foul brood as diplomatically and successfully as he did his feminine enemy, we think that he possesses qualifications that ought to recommend him very highly for the position. But personally we know nothing of the candidates for the inspectorship in New York—neither as to the men themselves, nor their special fitness for the position.

No. 2—ANOTHER POETIC BEE-ATTITUDE.—Scrib. Mag. Adv.

To Preserve the Aroma of Honey, according to a discussion reported in Canadian Bee Journal, it is important to seal it up as soon as possible. Any exposure to the air, unless for the sake of further evaporation, is a damage to the quality of the honey.

For Spring Feeding, Bee-Chat advises to let weak colonies alone, feeding only the strong colonies with syrup, and taking filled combs from these strong colonies for the weaker ones. Provident bee-keepers may do still better to have on hand a stock of combs of sealed honey, so no syrup need be fed.

Travel-Stain.—J. E. Crane reports that where old comb had been cut down and the bees had built out new, the part nearest the old comb was darkest, and the color changed to nearly or quite white at the edge farthest from the old comb. Also that the cappings in an extracting-super were dark if young bees had been reared in the comb, but white in combs that had not been used for brood-rearing.—Gleanings.

Sun or Shade for Wintering.—The editor of Schweiz. Bztg. found, as the result of observation, that a colony standing in a sunny place, on account of more frequent flights, consumed three to four pounds more from Nov. 1 to Feb. 1, and also had more dead bees than one in a shady place. That leaves it still possible, however, that in other localities the shady place might be the worse of the two. At least if the place is so shady that bees are confined too long.

Quinby's Idea of Size of Hives.—F. L. Thompson has been doing some figuring in the Progressive Bee-Keeper. Quinby's 2,000 cubic inches for a box-hive is by no means

the same as that amount of space in the body of a frame hive, for in the latter case a lot of room is taken up with the wood of the frames and the surrounding spaces. A 10-frame Langstroth would about suit Quinby's idea, as the space inside the frames is 2,100 cubic inches. An 8-frame hive has only about 1,670 cubic inches inside the frames.

Scholz (or "Good") Candy.—To make this candy, G. M. Doolittle thoroly warms good powdered sugar by setting it near the stove four to six hours, then good, thick, wholesome extracted honey is warmed till it feels quite warm to the hand; the sugar is stirred in till it can be worked by the hands, when enough of the sugar is kneaded in till the loaf will stand up without flattening down when placed on a flat surface. It is now set away in a warm room for a week or so, when it is ready for use; but if the weather is warm, or the queens are to go to a warmer climate, about 1/4 of the bulk of the candy must be kneaded in of fine *granulated* sugar, when it will not run, even at 100°.—Gleanings.

Wintering Bees in Colorado.—F. L. Thompson reports, in the Progressive Bee-Keeper, some points brought out in a discussion of Colorado bee-keepers. Single-walled hives are chiefly used, but chaff-hives or cellaring might pay well in saving bees and honey, if properly managed. He says:

"But chaff-hives should be painted a dark color, not have propolized or sealed cloths between the frames and top packing, not have too thick walls, an inch or two being sufficient between outer and inner walls, and should be examined at the conclusion of cold spells to make sure that the top packing continues dry; if not, it should be aired as soon as the weather is warm enough. One member reported that for three years in succession he had made tests of chaff-hives on a large scale with single-walled hives sitting along side, and every year found that the colonies in chaff-hives had enough more honey to pay for the hives. Another said he always had to remove honey in the spring from his chaff-hives, to make room for the brood; and that his cellar-wintered colonies consumed five or six pounds during the winter, while the others averaged 20. Another said that bees in his thick-walled chaff-hives, painted white, with the same quilts they had in summer, and left to themselves in winter, invariably wintered very poorly."

THE G. B. LEWIS CO'S BEE-HIVES AND SECTIONS

ARE MODELS OF PERFECTION.

This is the Verdict of Thousands of Customers and the Acknowledgment of Competitors.

Our unrivaled facilities, coupled with twenty-five years of manufacturing experience, enable us to anticipate and supply every want and need of the bee-keeper, promptly and accurately.

GENERAL ITEMS

A Long, Severe Winter.

My bees nearly all died during the past long winter. I think it was the longest and coldest winter I ever past thru. The first heavy snow here fell Oct. 13, about one foot deep where not drifted, and it did not lie long except where drifted, but it soon turned cold, and has been a very long, severe winter, the most so of any winter here known to the oldest inhabitant. I had 26 colonies of bees last fall, and now have just four. I am allowing them to build up on the honey left by dead colonies, taking off the covers and setting out from the live bees, some distance, and now think it is a wise Providence, as I could not attend to so many without help or overwork.

GEORGE McCULLOUGH.

Page Co., Iowa, April 13.

"Adel" Means "Noble."

On page 235, Henry Alley gives his explanation for the adel bees. He says, "adel means superior." If I am right, adel signifies noble, and adeliger means nobility. Adel is a German word and means something with a pedigree; Adeliger, meaning nobleman, is, to my mind, not superior to other people as man, tho he may be in his class in a far away land.

Bees are flying every day now, and doing well.
ALBERT WILTZ.

Atchison Co., Kan., April 16.

Weak Colonies - Little Clover.

Bees are working very hard now, bringing in pollen, but we have very many very weak colonies. Mr. Axtell says there is but little white clover left in this neighborhood.

Mrs. L. C. AXTELL.

Warren Co., Ill., April 26

A Rather Gloomy Outlook.

The outlook is gloomy. Bees, as far as I know, are gone from the smaller keepers. The larger ones have suffered, while bee-keepers of my type don't know yet how they do stand. I have 30 dead colonies, and the next 20 days will demonstrate what small colonies will do in maintaining their identity after a winter with no warm days in March.

Yesterday my bees had their first flight since the warm days in February, and it was so cool yesterday that none took wing till the afternoon, and then only for two hours. Of course, we are up in the clouds—1,200 feet above the ocean—and don't have warm days. All days are clear and bright here. We have little but sunshine; neither snow nor rain or clouds to compare with the southern part of the State. It is uniformly cool, and this March it was colder—a week near zero all the time, and 28 to 30 degrees below two mornings—10 degrees colder than for four years. I will write again after finding how things turn.

T. F. BINGHAM.

Clare Co., Mich., April 11.

Bees and Sorghum-Making.

In regard to the question of keeping bees and running a sorghum mill, my experience is much on the same line as that of Andrew Carlson, on page 109. I have worked the two together for eight years. My bees are about the same distance from the mill, but a neighbor keeps bees within three rods of the mill. The bees give no trouble as long as there are flowers to gather nectar from, but after a frost, followed by warm days, they come in large numbers, but we could control them with smoke. But last season was a heater. The summer was a poor one for honey, the flowers prac-

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with the order:

tically closing by June 20, and the bees were idle until sorghum-making commenced, which was Aug. 29.

The second day they began to come in swarms, and seemed to be perfectly wild after the sweet; they were into everything where there was juice or syrup unless tightly covered, smoke having no effect unless so dense that the hands could not work in it. They would fly into the steam, causing them to drop into the boiling juice. The juice-tanks would be covered with drowned bees.

At the mill they were the worst; some days they came in such swarms that I was compelled to saturate cobs with coal-oil, set fire and burn the bees. I confess it made my heart ache to destroy them when they were trying so hard to supply themselves with food.

Now as to the effect on the colony at the hive: I believe it is quite a benefit, as it stimulates the queen to laying and brood-rearing, thereby having a good supply of young bees to winter, for those that are destroyed are old workers, and would die before spring, and the sweet they store is all used before winter by the young brood, as I have found none in the cells when I prepare them for the winter, which is the last of November.

The loss of bees this winter from starving and freezing is heavy—from 1/3 to 1/2. Very few use chaff-hives, and none winter in cellars.
ORTON CONGER,
Shelby Co., Ind., March 29.

Hard Winter for Bees.

I have my bees—about 100 colonies—in the cellar yet, having lost a few during the winter. This has been a hard winter for the bees, in this location, on account of cold weather. A great many have lost all their bees.
SAM SEVERSON,
Clark Co., Wis., April 7.

Bees Building Up Well.

Bees that pulled thru the past winter are building up finely. Fruit is just blooming, and alfalfa is growing well. Otero County did not lose as large a percentage of bees as most places report.
F. W. CHAK,
Otero Co., Colo., April 25.

Visit to Louisiana—Lost None.

Last January I ran down to Louisiana on a visit to my old home, 48 miles north of New Orleans. I spent two days with my nephew, Edwin R. Wells, who has a very pretty home just a half mile west of town. The "queen" of this home, an intelligent and womanly little woman, and four or five children, make Mr. Wells one of the happiest of men. He is engaged in strawberry and vegetable growing, and bee-keeping. His vegetables and berries are shipped to Chicago, and net him quite handsomely. The product of his apiary, he told me, he could not so easily dispose of. His bees did very well the past season, storing a good surplus. There was served on his table, while I was there, some finely-flavored extracted honey of a light straw color. It was quite thick, but it never granulates. I was unable to ascertain whence the nectar was taken by the bees. He had Italianized his apiary about three years ago, but there being so many black bees in the forest and in neighboring colonies he was unable to keep his stock pure. One of the greatest depredators on his apiary is an immense dragon fly that comes during the spring and summer, just before sunset, and waylays the homeward-bound, heavily-laden little bees, and devours them with ravenous appetite.

Mr. Wells has promised to write me a list of the nectar-producing plants of that region, together with some of his experiences in a Louisiana apiary, which I may give to the readers of the Bee Journal, if considered worthy of interest.

Our bees here are in good condition, and out of 11 colonies, packed last autumn, we have lost none. I happened to be busy

WE

are kept very busy—the result of the satisfaction we always give our customers.

CHAS. F. MUTH & SON.

I wish to announce to my friends and patrons that I have this day sold to C. H. W. WEBER, of Cincinnati, my Honey and Bee-Keepers' Supply business, known for the past 38 years as **CHAS. F. MUTH & SON.** Mr. Weber will continue to push the Langstroth hive and everything pertaining to same; besides, he has secured the agency for Mr. Root's goods, and will sell them at his prices. I beg the customers of the old house, to whom I wish to extend my thanks, to continue their patronage with Mr. Weber, by whom I am sure they will be accorded fair and honest treatment.

MRS. ANNIE MUTH (Widow)

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman. It is a nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apian library is complete without this standard work by Rev. L. L. Langstroth the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

ABC of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohnke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others. Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

York's Honey Almanac is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey. A very effective helper in working up a home market for honey. Prices: A sample for a stamp; 25 copies for 40c; 50 for 60c; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00 For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

cribing a large crop of corn at the time the bees needed fixing for winter, so Mrs. Durbin gave them her attention, and without assistance from any one arranged them so comfortably that they past safely thru our unusually severe winter, with the mercury running down to 28 degrees below zero. They are on the summer stands. It is too early to prognosticate for the coming season. Wm. J. DURBIN.
Fayette Co., Ind., April 12.

Substitutes for Pollen.

We would like to exchange some rain for sunshine just now. Our bees are not getting any pollen, and have not been for about three weeks, consequently they are not rearing any bees. So we fear they will not be in condition to make the best of the honey-flow which we usually have in May, from poplar, willow, black locust, blackberries and dewberries.

Dr. Miller recommends giving bees a mixture of oats and cornmeal, and from reading bee-books and papers I have been led to believe that flour, meal, and such mixtures could and would be used as a substitute for pollen. So with the idea untested, I have been giving my bees corn and oatmeal mixt. I also put flour where they could get it. They seem to like flour the best. I will add that this is the first time I ever noticed that bees could not get all the pollen they needed.

I would like to ask Dr. Miller or any of those who have been telling beginners to feed corn and oatmeal, flour, etc., what good does such stuff do the bees? It certainly is no good as a substitute for pollen, or larva food, for I have several colonies at this date in which there are from one to three Langstroth frames filled with eggs, and have been for the last 15 days, and yet there are no young bees in any of the combs. This rather puzzled me, and I took some of the combs of eggs out and gave empty combs, and the queen would at once fill them with eggs.

One might think it would not be taken by them unless it could be valuable in some way, but such proof is not worth much, for they will take fruit-juice, sorghum or almost anything that is the least bit sweet, in times of scarcity, yet almost any bee-keeper of experience can tell you that bees will not thrive on them. I do not know of any good it can be to them, unless the old bees use it as food, and I am not sure they would not be better off without it.

My bees have carried several pounds of meal and flour into their hives without any apparent benefit. So if there is any good in feeding corn and oatmeal, flour, etc., let's know what it is. C. PRESSWOOD.
Bradley Co., Tenn., April 11.

Albino Bees—Loss of Bees.

EDITOR YORK:—I see several are asking for a description of the albino bees. By this mail I send you a cage of my albinos. You rather intimate they are lacking in vigor, or color-matter, which would convey the impression that they are an inferior race or strain. I have had this strain of bees for the last six years, and in the past 12 years I have had queens of every and all the different strains and races now in the United States, except the Punics; I have had queens from nearly all the prominent breeders in the Union and Canada; and I consider, taking all points, the albinos the superiors of the whole lot. Because their hair is white I can't see why that should lessen their vitality.

I now have an old white mule which my father bought when I was a boy. He (the mule) is now 29 years old, and the past winter he helped to plow 50 acres of land for corn, and is far better than many black, sorrel, and bay mules I know. Surely, his white hair has not lessened his vitality.

Because the albinos have white hairs on their abdomen, and rather a bluish hair around their shoulders and head, I can't see why that should weaken their constitution; and as the regular Italians have a

faded yellow or dirty brown hair, why this color should make them more bardy.

The general report is that more bees were lost the past winter in Texas than was ever known before. I wintered 100 full colonies and several 4-frame nuclei without the loss of one, all on the summer stands and no protection whatever, altho the weather took a tumble in February from 70° above to 10° below zero in 24 hours. J. D. GIVENS, Dallas Co., Tex., April 17.

[The bees were received and are nice in appearance. A thoro trial, such as Mr. Givens has given the albinos, ought to have some weight. We have no doubt that they are good bees, but certainly no better than some others because they have a sort of whitish hair on their bodies.—EDITOR]

Convention Notices.

Illino's.—The Northern Illinois Bee-Keepers' Association will hold two sessions of its spring meeting, one at Mr. John Wagner's, near Beuna Vista, Stephenson Co., under the supervision of the Vice-President; and one at Mr. Oliver Taylor's, at Harlem, Winnebago Co., in charge of the President, on Tuesday, May 16, 1899. Every one is cordially invited. B. KENNEDY, Sec. New Milford, Ill.

Texas.—The Central Texas Bee-Keepers' Association will meet at Milano, Tex., July 29 and 31, 1899. All are cordially invited to attend. H. H. HYDE, Asst. Sec. and Treas. Hutto, Texas.

Colorado.—A joint meeting of the Colorado State Bee-Keepers' Association and the Denver Bee-Keepers' Association, will be held in room 33, second floor of the Capitol Building, in Denver, Wednesday, May 10, at 10 a.m. Amendments of the Constitution and By-Laws, and other important matters, will be brought up. MARSHFIELD, WISCONSIN.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, April 18.—Best grades of white, 13c; off in color, etc., 11@12c; light amber, 10@11c; dark amber and mixt buckwheat, 7@9c. Extracted, clover, 8c; other grades of white, 7@7 1/2c; ambers and dark, 6@7c. Beeswax, 27c.

Sales are in a small way, as the time of year is with us which usually sees the close of active sales. Owing to the inclement weather which has cut off the early fruits and vegetables the honey market has benefited, so that all of the white comb is nearly disposed of. There is quite a quantity of dark and undesirable comb being offered.
R. A. BURNETT & CO.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10@11c; dark and amber, 8@9c. Extracted in fair demand without change in price. Beeswax, 25@26 1/2.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey.
M. H. HUNT.

NEW YORK, April 19.—Fancy white, 12c; No. 1 white, 10@11c; amber, 9c; buckwheat, 7@7 1/2c. Extracted in good demand at unchanged prices. Beeswax quiet at 27c.

Our market is well cleaned up on comb honey. There is a fair demand, especially for white.
HILDRETH BROS. & SEIGELKEN.

SAN FRANCISCO, April 5.—White comb, 10@10 1/2c; amber, 7 1/2@9c. Extracted, white, 7 1/2@7 3/4c; light amber, 6 3/4@7c. Beeswax, 26 1/2@27c.

Beyond a small jobbing trade, mainly out of supplies in second hands, there is nothing to record in the way of business. There are only moderate supplies, and these are mainly comb. Values are steady. It is too early to get definite information concerning coming crop, but it is not likely to prove large in this State.

BOSTON, April 18.—Fancy white, 13c; No. 1, 11@12c; A No. 1, 10@11c; light amber, 9c. Extracted, stocks about cleaned up. Nominal price for white, 8c; for light amber, 7c. Beeswax, very light stocks; selling at 27@28c.

Naturally the demand for honey is gradually growing less, and also stocks on hand are not large, still the demand is so small that the general feeling is weak and prices are being shaded in order to work off stocks.
BLAKE, SCOTT & LEE.

KANSAS CITY, April 6.—Fancy white comb honey continues in good demand at 13 1/2@14c; choice white at 12 1/2@13c; dark, 10 1/2@11 1/2c. Extracted scarce at 6 1/2c.
PEYCKE BROS.

CLEVELAND, March 9.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.
A. B. WILLIAMS & CO.

BUFFALO, April 21.—Our market is cleaned up on fancy comb; more would bring about 12 cts. There are more or less very poor lots selling at 7@8 cents, at which quite a large amount can be sold. Extra fancy beeswax, 28@30c.
BATTERSON & CO.

OMAHA, April 18.—There is but little stock left in dealers' hands now, and realizing that no further receipts can be expected until another crop gets into the market, it is held firm at 14c for fancy white comb. Extracted, 7 1/2c.
PEYCKE BROS.

MILWAUKEE, March 2.—Fancy 1-lb. sections, 13@14c; A No. 1, 12@12 1/2c; No. 1, 11@12c; dark or amber or old, 7@10c. Extracted, in barrels or kegs, white, 7@7 1/2c; dark, 5 1/2@6 1/2c. Beeswax, 25@27c.

Since our last report we have had a very good market for honey, and the demand has been very good for all grades, especially for sections of the best quality, and the demand is good now and small supply. We encourage shipments of best comb. Extracted, fair demand.
A. V. BISHOP & CO.

Nuclei of Bees For Sale.

We have arranged with a bee-keeper in Lee Co., Ill., about 100 miles west of Chicago, to fill orders for 3-frame Nuclei of Italian Bees, with Queens, at \$2.75 each, or in lots of 5 Nuclei, with Queens, at \$2.50 each. Orders can be filled about May 10 and after.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

Order Early

There are indications that the demand for SUPPLIES will be very large this season, and everyone should order as early as possible. We have large facilities for manufacturing all kinds of

Bee-Keepers' Supplies,

And will serve our customers as quickly as possible.

Falcon]Sections are the Finest Made.

1899 Catalog ready Feb. 1. Copy of the AMERICAN BEE-KEEPER 20 pages, 1tee. Address

The W. T. Falconer Mfg. Co.
JAMESTOWN, N. Y.

I ARISE

To say to the readers of the BEE JOURNAL that

DOOLITTLE...

has concluded to sell QUEENS in their season during 1899, at the following prices:

- 1 Untested Queen \$1.00
- 6 Untested Queens.. 4.50
- 12 Untested Queens 8.00
- 1 Tested Queen 1.50
- 3 Tested Queens.... 3.50
- 1 select tested queen 2.00
- 3 " " Queens 4.00
- Select Tested Queen, previous season's rearing, \$3; Extra Selected, for breeding, the very

best, \$5.00. About a pound of Bees in a 2-frame Nucleus, with any Queen, \$2.00 extra. Circular free, giving full particulars regarding each class of Queens. Address,

G. M. DOOLITTLE,

CONVENTION PROCEEDINGS

Report of Wisconsin Bee-Keepers' Convention.

[Continued from page 278.]

The three following papers were read by those whose names are signed thereto:

Future Prospects of Wisconsin Bee-Keeping.

We can only judge the future by the past. For the past 20 years the price of honey has steadily declined. It is true, prices were higher in 1898 than in 1897, so also in every season of very short crops. Still, the general tendency is downward, as will be seen if we look at quotations for a few years past, taken in December of each year:

| | Comb honey. | Extracted honey. | |
|-----------|---------------------|--------------------|--|
| 1881..... | 14 to 22 cents..... | 8 to 10 cents..... | |
| 1883..... | 14 to 20 cents..... | 8 to 10 cents..... | |
| 1885..... | 13 to 16 cents..... | 6 to 8 cents..... | |
| 1886..... | 10 to 13 cents..... | 6 to 7 cents..... | |
| 1889..... | 10 to 15 cents..... | 6 to 7 cents..... | |
| 1890..... | 12 to 15 cents..... | 7 to 8 cents..... | |

From 1890 to 1896 a little decline each year.

| | | | |
|-----------|---------------------|--------------------|--|
| 1897..... | 8 to 12 cents..... | 4 to 6 cents..... | |
| 1898..... | 10 to 13 cents..... | 5 to 6½ cents..... | |

The lowest prices we have ever seen were in 1897, when there was a good crop over a large portion of the country. The crop of 1898 was very short, and the advance of prices was from one to two cents per pound.

The improvements in methods and appliances may have had some influence in increasing the quantity, and consequently cheapening the cost of honey. The diminished profits of other pursuits has induced many to engage in bee-keeping who would not otherwise do so, and thereby helped to fill the markets and drag down prices.

I have noticed that whenever a good crop brings down the price in any of our small villages or cities the decline becomes permanent. A poor crop the following season will not restore prices. Whenever two or more apiarists bid down the prices for their own town, they cannot easily advance prices in that town again. An advance of one cent a pound induces many to dispense with it who would willingly pay a fair price if they did not know it had once been sold cheaper. This being true, according to my observations, bee-keepers should be slow to undersell their neighbors in the home market.

There is also noted a tendency toward higher prices for supplies, which affects profits, but I hope this will be of short duration.

Against these discouraging thoughts we may find some encouragement in the thought that more honey is being

consumed by the working people; this increase of consumption I think is likely to continue. We are hopeful of legislation that will tend to suppress the adulteration of honey, and this will increase the consumption of honey by giving people confidence in the purity of what they are buying.

Any improvements either in packing or transportation that will enable us to ship comb honey without smashing it will help to increase consumption and strengthen prices. I am confident the majority of producers don't know how badly their comb honey looks after it has been shipped even a short distance by railroad, especially in cold weather.

All things considered, I look for lower prices for two or three years to come, but not much below the prices of 1897. Juneau County. F. Wilcox.

Handling and Shipping Extracted Honey.

Some seasons extracted honey should be handled differently from what is necessary in other seasons. For instance, last season, in my locality, almost any way of handling it would have been successful, because the honey as soon as stored in the combs was very thick, so that it would

Pres. F. Wilcox.

strain very slow thru cheese-cloth while yet warm. Presumably, the cause of it being so thick when gathered was on account of the very dry weather during the honey-flow, which is nearly all from basswood bloom.

My mode of handling honey when in the above condi-

tion is to have a funnel large enough to hold a pailful, with the small end just the right size to fit in the bungholes of the barrels or kegs that I wish to store the honey in. Then have a cheese-cloth strainer large enough to tie over the top of the funnel and bag down into the funnel enough so that it will hold a pailful. Put the funnel into the barrel or keg tight, then draw from the extractor a pailful and empty it into the funnel. While that is straining you can be extracting more. When the barrel is full, bung it up and let it stand in the honey-house, or any other dry room, until ready to ship.

But in the season of 1897 the honey was thin when gathered by the bees, and during basswood bloom it came in so fast that the hives were full before any of it was fit to extract. After having used all the supers I either had to extract some to give them, or else let the bees lie idle while the honey was ripening. So, rather than have them idle, I extracted a few combs from each hive every two or three days, taking the best combs, or the ones that had the most sealed honey, each time, and stored it in kegs, and put cheese-cloth over the bungholes for ventilation; and yet, after taking all the care of it that I knew how, about 1,000 pounds of it soured.

Since having the above trouble, I have bought two galvanized sheet-iron storage-tanks holding about 1,800 or 1,900 pounds each, to use for holding honey, particularly any honey that I think is not well ripened before extracting. Then, after standing in the tanks a few days, or until I have to put more honey in the tanks, I draw it off from the bottom of the tank thru the faucet, and fill into barrels, or whatever I want to store and ship the honey in.

My experience is, that honey after standing in kegs or barrels will partially separate—the heaviest and best will be at the bottom of the barrel, and the poorest and thinnest will be at the top. These storage-tanks being 4½ feet high, give a good chance to draw off the best of honey, and leave the poorest in the tank; then what poor honey there is can be put by itself, and not have a little poor honey in every barrel.

For convenience in handling, I prefer barrels, kegs or kits. I have handled thousands of pounds in 60-pound tin cans, crated two in a case, and consider them the most unhandy and inconvenient package to handle extracted honey in that I ever used. It takes more muscle to handle them with ease than I have. You dare not end them over for fear of smashing the box; they won't slide worth a cent; and it makes me red in the face to pick one up and carry it. Barrels or kegs can be rolled into or out of a wagon quite conveniently, and 30-pound kits can be picked up one in each hand and carried easily.

I have shipped honey to 10 or 12 different States, and I have had no reports of leakage or loss in shipment, consequently I have not had much experience (that is, not much *bad* experience). Before shipping I always drive the hoops tight, then nail the chime hoops with three or four penny nails. I drive the bungs tight, and saw them off even with the head. I put plain directions on the shipping-tag, and tack it fast to the head of the barrel. G. W. WILSON.

Vernon County.

Selling Honey.

To one who would engage in the pursuit of bee-keeping the numerous text-books supply all the needed information as to how to handle bees so as to attain the best results. But when the crop is secured, these same books fail to give any instruction as to how that crop is to be disposed of. The reason is obvious: Different circumstances and different localities require different methods. It is not, therefore, my purpose to lay down some set rules for the successful selling of honey, but rather to give some results of my experience in that line, hoping, in the discussion that will follow, to profit by the experience of others.

And at the start I would submit to you the proposition that honey is not a staple but a luxury. While it is true that some people use it daily, and may regard it as an article necessary to their table, it is also true that such people are like angels' visits—few and far between. In my whole acquaintance I know of but two, and they both belong to the same family.

While times are good and money is plenty one can dispose of honey very easily, but let the crops fail, and economy become necessary, honey will always be found among the first articles to be put on the retired list. Such being the fact, it follows that in the case of honey, more than in that of any other article of food, customers must be hunted after and not waited for.

For me, it has always been easier to sell comb honey. There may be several reasons why people prefer it. In the first place, because of the looks, for what is prettier than a nice, full section of white honey? And that leads me to submit another proposition: With very few exceptions honey sells more by looks than by taste.

Then, comb honey, if properly cared for, will not change its appearance, while the extracted will after awhile candy, and whenever that happens, people look on it with more or less suspicion. I have had store-keepers tell me that my honey had soured(!). Getting them to put it on the stove a few hours soon convinced them of their mistake. Besides, the flavor of comb honey will not be affected by the lapse of time, while the extracted will after awhile be found to have a different flavor from what it had at the time of extracting. (On this point my experience is limited to basswood honey.) Then it has a mild flavor; for me it is the most delicious honey in the world; later on it takes a strong minty flavor, which is disliked by those who are not used to it.

In order to realize a good price for comb honey, it is essential to have it reach the market in good shape. I have found that 12-pound cases, showing three sections, are preferred in the large cities. Such I fill with sections of the same quality, putting the nicest side next to the glass. I always make it a point to so arrange it that the sections can be taken out easily, nailing the covers with smooth nails, not larger than one inch. I ship by freight always, using crates holding 18 cases, which crates have handles, and my honey has always reached the market without breakage.

I mark the boxes with my name and address, and weight, putting it an ounce or so below actual weight, for honey will lose a little if kept three or four months. I have never yet used labels on sections, but I am inclined to think that it would be a help, and propose to give them a trial next season.

In disposing of my crop I have had the best success while working up my home market. For the same kind of honey I often get a better price than in the large cities, and certainly so if I count the commission, which I save by being my own salesman. Besides, the home market does not grade honey so closely as commission men do. In my neighborhood only two grades are recognized—the dark and the white, with a difference of only two cents between them.

Another thing in favor of the home market is its steadiness; mine has not varied more than 2½ cents in nine years for comb honey, and has been at the same price for extracted.

The home market is also the place to dispose of all the off grades. Once I sold about 400 pounds of such to a store at 7½ cents a pound. It netted me a little over \$30, which I thought was better for me than extracting or feeding.

What I said about the home market for comb honey will apply equally well to extracted honey. One that has never tried it will be surprised to find how much extracted honey he can dispose of in his own neighborhood; but to succeed one must be persistent, neglecting no one, for in the same town some stores would have a constant sale for my honey, while others would not handle it, having a different class of customers.

The style of package used may have some importance. After several trials I prefer now the one-quart Mason jar. It will show off the honey to the best advantage, and when empty it is always useful to the buyer. If kept too long, and it candies, I replace it at my next visit. I believe that honey would sell more freely in a smaller package, that would be retailed for 10 cents, but a great objection to such is their increase cost compared to the value of the honey. I once tried glass tumblers with tin lids, but altho I sold a goodly number, I soon gave them up on account of the work involved in filling them. Muth's glass bottles, which might do for a fancy trade, would not sell in the country because of their cost.

It has always been easier for me to effect sales after becoming acquainted with prospective customers, for I found the fear of adulteration very prevalent among the people, and there has been good ground for that feeling. To my own knowledge a Milwaukee firm has sold a large quantity of so-called honey, put up in pint jars, selling it at the same price I was offering mine. I have found it in Watertown, Jefferson, Fort Atkinson and Whitewater. Since the new law has taken effect, it has almost disappeared, for it has to be labeled adulterated or mixt.

After the home market has been supplied, and there is some honey left, one may have to send it to the large cities to be sold on commission, but I would do it only as a last

resort, as I cannot say that I have ever been entirely satisfied with the result. In trying to find a new outlet for my crop I even shipt some to Europe. What induced me to do so was the high prices obtained there. While on a visit to Switzerland two years ago, I saw extracted honey sell for 24 cents a pound, but my attempt was not entirely successful. I had sent basswood honey, but most people did not like its strong taste. I think the result would have been different if I had shipt clover honey, as I had at first intended doing.

We have seen the price of honey getting lower year after year, until it is very near the point where the price obtained will hardly cover expenses. I attribute it to the fact that production has been greatly increased with the better knowledge of apiculture, while the consumption has not kept pace with it. How to find a remedy for this state of affairs is a problem that is very important to the bee-keeping fraternity. A more equal distribution of our crops after securing them, and more reliable reports of the yield in different parts of the country, would, I think, help us greatly in answering this hard question. And I indulge the hope that the honey exchange, which is being tried in California, may be found to work well, and its operation be extended thru the whole country.

Jefferson County, GUSTAVE GROSS.
[Concluded next week.]

The Afterthought.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

PERCENT OF WAX IN COMB HONEY.

Of course I see Mr. Aikin's invitation, on page 227, to get down on my knees—and play checkers. Thank you, Mr. A; but I do not kneel at games—except possibly when seeking to win a queen—and there are no queens in checkers, I believe. Well, I honestly got it that you claimed it took three pounds of wax to fill the sections holding 25 pounds of surplus. You didn't say so. What you did say was reasonably clear—two pounds below and *one* pound in the sections—and yet I didn't "catch on." At the time I penned that criticism I think I must have been forcing myself to write when my mind was not in condition for any such business.

A CASE OF KEEPING ALL COLONIES WEAK.

Singular that Prof. Cook, who has done so much to popularize the motto—"Keep all colonies strong"—should, on page 194, come to the front with the advice to keep all colonies weak (in famine times in a warm climate); but it looks as if he was right in this reversal of the doctrine. That young queens reared in famine times would be better than the old ones is not quite so clear, but may be all right if the apiarist "knows the ropes."

BEEES ON PEACHES ALL NIGHT.

Mrs. Axtell's observation that bees at work on peaches some times seem stupid, and often stay all night on the fruit, is of interest. It is well known that the leaves and kernels of the peach carry considerable poison; yet we should hardly expect the fruit to contain enough to stupefy bees. Whether she would have succeeded in getting peach-juice and white-sugar syrup mixt by feeding the latter when they were gathering the former—well, next time she must try it and report. You see they *might* abandon the peaches if they had syrup enough to store. Page 195.

TIME NEEDED FOR GREAT REFORMS.

I wonder if Doolittle isn't drawing it too fine, on page 196, when he says that the effort that the thief puts forth in gaining his swag is *not* labor. Some of our brothers and sisters in the craft, who worked hard last summer, may take this grain of comfort, that it wasn't labor (produced nothing). But I suspect Doolittle is about right in his main contention. In this one matter he's a little "off," I think, *seeming* to blow cold on anti-adulteration efforts. Bee-keep-

ers alone, without joining teams with the rest of humanity, could abate the adulteration evil to a great extent. As our interests all lie in that direction, it looks like a *practicable* scheme. A scheme that cannot succeed till it has a majority of the entire electorate enlisted looks, if not impracticable, at least rather remotely practicable. Big job to right our political and financial evils—even as it's a big job to put down the liquor evil. All these things will be set right some day; but to say, Stop catching that one lark till the sky comes down and we get all the larks well, that's the style of some people, but not a wise style.

FEELS LIKE DOFFING HIS HAT TO A HIVE-MAKER.

I feel like taking off my hat to Mrs. Griffith (page 206). To make in one day six hives all ready to paint by sawing and reconstructing dry-goods' boxes is a remarkable achievement for a woman coming 70. I am not a woman, and not 70; but I am such a mechanical "non-possom" that I fear I should require a whole day to make one—and then it wouldn't be a good one. And I'm not advising the sisters to follow Mrs. G.'s method of providing a supply of hives, unless they feel strongly inclined that way.

LETS SCOLDING BEES ALONE.

On the question whether to knock down persistent scolders or not (page 202, paragraph 9), my experience favors letting them alone. Rather seldom do I get peace by killing them. Kill three, and directly there'll be four or five.

THE V-EDGE HOFFMAN A HIVE-LEVER.

Comrade Davenport's argument against the V edge of the projection on the Hoffman frame seems to be valid. Bees quickly put on propolis enough to make it as thick as the corresponding edge is. Then it catches bees fully as badly as all square edges would, and cannot be cleaned nearly as well. Page 209. But I laughed when I heard him say of his pet hive-lever and hook, that its *main* advantage was that it could be hung on the edge of the hive. Probably he didn't mean exactly that.

TO PREVENT SWARMING MUST PREVENT QUEEN-CELLS.

I guess Edwin Bevins is right, that to prevent swarming we must prevent queen-cells. With these once tentanted, nothing short of a long spell of very bad weather will cause them to be torn down.

KEEP POULTRY OUT OF THE APIARY IN WINTER.

W. W. McNeal sets us a wise saw when he tells us not to let fowls use the apiary as a loafing-ground in winter. They thump around the hives to such an extent that many bees come out of the cluster and perish. Page 211.

CANDYING OF GOOD, WELL-RIPENED HONEY.

H. P. Wilson thinks that "good, well-ripened honey is slow to candy." Probably right, if the strict meaning of the words is adhered to; but some may use those words in the sense that good, well-ripened honey doesn't candy at all. If that idea should be pushed, there would be a numerously-attended row in our camp directly. Page 212.

QUEENS REARED IN SMALL COLONIES.

I see on page 213 the Chicago convention wrestled with the question *why* queens reared by just a few bees are inferior—too cold—too small a supply of food. Perhaps I can add a little (to the theory, that is.) The queen-larva is capable of taking a large share of its food by absorption, right thru the pores of the skin. In so far as it feeds in this way it can select—or perhaps "filter"—would be the better word—taking the richer parts of the jelly and leaving the grosser; and thus the great lot of jelly left is not entirely waste, as it looks to be. Diminutive colonies never supply jelly in such plenty—it's "eat what's set before you, and eat it all."

THE HONEY-DREW DR. MILLER DRINKS.

I'm afraid Dr. Miller's example, in using granulated honey-dew in preference to sugar in his coffee, will not be followed largely enough to create a market. Interesting to see that there is such a honey-dew product that can be so used by a good judge.

COWS EATING SWEET CLOVER ROOTS.

I think the most unique and interesting thing in the beedom boil of page 218, is the sweet clover paragraph—those cows that for weeks pulled and ate sweet clover roots from the plowed ground. Nature is not inclined to waste its weapons. There are no thorns on roots; and if any

taste is simply for defense, to disgust above-ground eaters, it would not be surprising if roots should be free from that taste. . . . I've just been out to get a sweet clover root to eat. I find the leaves have the most pungency, the stems somewhat less, the roots still less, but yet not free from the distinctive flavor of the plant. The roots seem to have a *sweetness* in addition, which probably "fetcht 'em." But if I were a cow I'd be *ashamed* to kick at either leaves, stems or roots.

JOSIE THE HONEY-EATER—HE OR SHE?

That 13-year-old Josie, on page 222, who oft eats a pound of honey just for appetite's sake—is Josie a boy Josie or a girl Josie—that's what I want to know?

HONEY IN PRESERVING FRUIT.

Bevins' trials of honey for preserving fruit (page 221) seem to show that it will work in the style of extra-sweet pickles, but not alone on raw fruit. I made some grape-jelly with honey last fall—damaged the honey, without benefiting the grape-juice to any great extent.

FRUIT-BLOSSOMS AND BEES.

I protest (with due modesty, of course) against the first editorial quotation on page 217. It's an ancient chestnut to begin with—and, to end with, all bee-folks ought to know that putting a hive of bees right under a tree does not secure its flowers any more bee-visits than if the hive was a quarter of a mile away. Field-bees rather *prefer* to fly a short distance. What kept the bees off that tree the previous 25 years is surely quite a mystery. Most bee-folks do know these things, after a fashion; but when political editors and other outsiders give us taffy we tumble, and lose our heads altogether too easily. The circulation of thinly-disguised nonsense tends to make the public think that all our claims are nonsense—which is far from being true—in fact, *some* of the claims of that quotation are O. K.

COGITATOR.

Spring Management of Bees in Large Hives for Extracted Honey Production.

BY C. P. DADANT.

A SUBSCRIBER desires my ideas on the management of large hives for extracted honey for six weeks previous to the expected honey-flow. I believe that my last articles on spring management would express the most important part of the system I would advise. To harvest large crops we need bees, and those bees must come at the right time. If the breeding of bees on a large scale does not begin till the opening of the honey crop, and if this crop is short, say three weeks in duration, the bees will have been reared to no purpose. It takes just about three weeks to develop a honey-bee from the time the egg is laid; and all, or nearly all, our naturalists tell us that the bee does not become an active field-worker till about a week after emerging from the cell, except in extraordinary circumstances, such as the departing of a swarm or the deprivation of the hive of its old bees by artificial swarming, which renders it imperative for some of the bees to volunteer in search of stores before the time set by nature. Thus the reader will see that about a month elapses before the bee is of use to its colony. Then it is fit that we should by all means induce an increase laying when we foresee a crop in the near future.

In late seasons, when the inducement to lay is retarded by the natural circumstances, yet the impetus given is greater when it does come, for the reason that the number of blooms that come out at once is of greater variety. For instance, in early spring the willow is first to bloom, then comes the gooseberry, then the peach, then the apple, etc. These blossoms follow each other with intervals, during which the cool days again retard the laying, so that altho the inducements offered to the bees are oft-repeated, the alternates of cold and heat, of bloom and dearth, make the laying irregular. In a late season the weather warms up suddenly, but remains warm. The willow, the gooseberry,

the peach, and the apple bloom so suddenly that one blossoming merges into another, and the push is steady and vigorous. So the disadvantages of a late season are somewhat made up by the steadiness of its action. In our locality we have never seen the vegetation so belated and so suddenly active as this year. The last of the snow disappeared April 10, and we thought we were about to see the latest fruit-blooming we had ever had. But by the 15th, or five days later, the whip-poor-wills were whistling in our woods, and the fruit-bloom is now as far advanced as in average seasons.

But if we can, by artificial means, by oft-repeated feeding early in the season, of small amounts of food, induce our bees to breed early, they will be the better prepared to increase their brood-nest at the first warm days, and the bulk of our bees will be hatched out of their cells before the flow. This is the only secret of success.

Compare two apiaries in which different plans are pursued. In the one the bees are left to themselves without shelter, perhaps without sunshine if their location is in an unfavorable spot. Their supply of honey is scant because they have been too closely robbed by their owner the previous fall. They must stint themselves, they dare rear but little brood until they are sure of a coming harvest close at hand. They linger along, probably dwindle some in numbers, till the first bloom appears, but they cannot rear brood largely till there is actually some honey to be found in the bloom. With the best efforts that they can put forward they will not begin breeding to the full capacity of their queen until the opening of the real harvest, and they will be booming just in time to close the season with a small crop of surplus to their owner.

Now, the other apiary will give us a different story. The hives have been left with plenty of stores in the fall, they are well sheltered, they have all the sunshine that is to be had. The first warm days find them ready to work. They need not stint themselves since they have yet a surplus. So the least inducement in the way of pollen-bearing bloom encourages them to spread out, even tho no honey is yet to be had in the field. When the fruit-bloom begins they are sufficiently strong to give their queen the freedom of every comb, that is, sufficient warmth on every comb to enable her to lay eggs anywhere; they "horsewhip their queen," as some of our friends would call it. No, the queen does not lay any more in that hive than in the hives of the late-breeding apiary if the hives are of the same size, but she lays at the right time. The push comes so that the hatching bees are in time for the feast, and help harvest the crop instead of helping consume it.

There is nearly always an interval of about three weeks in this latitude between the fruit-bloom, which only incites breeding, and the real honey crop from clover, basswood, etc. It is during this interval that the thriving colony builds itself, and it is only the colony that thus builds itself, upon which we may safely depend for a bountiful harvest and a reward for our cares.

I think I have said enough to show what is needed previous to the harvest. In another article I will speak of what is done when the harvest is on.

Hancock Co., Ill.

Large vs. Small Hives in Kansas.

BY WM. H. EAGERTY.

IN looking over the articles written by Mr. Dadant for the American Bee Journal, I wondered at his patience in making the statement so often in regard to the large hive as used by him. I have used both large and small hives, and I know that the bee-keeper is, and will be, pleased with the work done by a prime swarm when put into a hive of moderate size, and for the first season the swarm doing so much better than the bee-keeper expected, but from actual use of both large and small hives, I will take the large one, every time.

Of course, there is a difference between the work done here in Kansas, where we have no white clover, and our honey-flow is mostly from fall flowers with a fine flow from sweet clover and alfalfa. The bees here must be strong the whole season thru, and it takes a good deal of honey to carry the colony over winter, but those large colonies in large hives pay well for all the honey they eat; and while it takes them some time to build combs in the brood-chamber, they "get there" every time when the work is once over; while the old colony in the small hive has not room the second season for both brood and honey in the brood-

combs, and is short of bees for the field-work. Of course, in other localities, where the white clover is plenty, and the honey-flow is early and strong, a small hive can be used to good advantage, and the bee-keeper who has never used one of our mammoth hives will be pleased with his small hive.

But take a hive holding 10 frames 10 inches or more deep, and 18 inches long each, and with a good queen—if there is any honey to be had, you will be very apt to get your share of it, and you will not have to lie awake nights figuring how to have your colony strong enough just at the right time. Your only wonder will be at the stream of bees as they come and go at the entrance of the hive, how the box can contain them.

I have kept bees for several years, and never extracted any honey, and I hear very much said about small hives being the best for comb honey, but I know the value of large hives and very strong colonies of the very best strain of Italian bees, for I think that there is as much difference in the quality of honey from different strains of bees as there is in the quality of butter from different cows that are fed in the same pasture. I am foolish enough to think that the bees "make" honey, adding an animal oil to the nectar while they pump it in and out of the cells of the comb. But of course I know they cannot change it very much in one of those very fast flows, as from linden or clover.

Republic Co., Kan.

The Longer Tongue Gets the Best Nectar.

BY A. B. BATES.

THERE may be perplexities in the communication I wrote on page 19, and there may be something like discordance in the third paragraph that seems fatal to the facts embodied in the article, as Mr. Bevins claims on page 134, but I am frank to admit I am unable to see it.

If I am correct in the statement, that nectar is heavier than water, I am also correct in the statement that the richer of the saccharine substances settles to the bottom of the flower-cup.

Since Mr. Bevins does not doubt the superior quality of the Italian product, but seeks to find the cause, I will refer him to the bee's tongue as the only cause that seems to me possible. While some blacks may have longer tongues than others of their own class, and while the very best of this black race of bees may equal or excel the poorest of the Italians, it does not signify that the Italians as a class do not excel largely the blacks as a class.

The tongue of the bee is certainly its most important factor in the work of honey-gathering. The long-tongue strain, in my opinion, lives longer, stores more honey, and of a rich quality in flavor and in sweetness than does the short-tongue strain; and when we find a colony of bees surpassing another with like strength and opportunities, in quantity, we may find like excellency in the quality of their honey also; and had we the ability or means to do so, we might locate the cause in the tongue.

Now, Mr. Bevins (I suspect you being a member of that order that you say is seeking more light), let us reason together, and it may be that the hood-winks may fall from our eyes.

When there is a meager secretion of nectar it remains in the bottom of the flower-cup, and if the bee's tongue is too short to reach it, you know the result. If the bees can barely reach it without any margin to go on, they must visit so many flowers before they can fill their honey-sacs that their pent-up energy, that constitutes their lives, is exhausted, and the honey stored being gathered from the watery part of the nectar is inferior both in flavor and in sweetness. The longer-tongue strain being able to reach to the bottom of the flower-cup fill their honey-sacs from a few blooms, with a richer quality, and with probably less exhausted nature, less wing-splitting, etc.

Regarding the flower-cup that is inverted or turned downward, how do they compare with those that turn upward, for it is the general bloom that we are to look to and not the exception? I have not been as observing as I should be, but I believe the basswood bloom is turned downward, and in the nectar-secretion by this bloom all strains have the same tongue ability, and should you find the quality to be the same coming from this source, and that the quantity is altogether conditioned to the population of the colony, will you not believe that the long tongue is the cause of the superior quality of honey stored from the general bloom in favor of the Italians?

Section-Cleaning Machines—Some Experiments.

BY C. DAVENPORT.

AS I have spent considerable money and time in making and experimenting with section-cleaning machines, I will describe the results and conclusions I have arrived at in regard to them, for by doing so it may save others time and expense in going over the same ground.

In the first place, tho, it seems locality must make a difference as to the kind of propolis gathered, for sand-paper of any kind, no matter how fast the disk or wheel is revolved, is entirely impracticable for removing such glue as is put on sections in this locality, either when it is first gathered or years afterwards.

Some time ago an article in the Bee-Keepers' Review described how the writer met with success by using an emery wheel. While there are, if I am right, about 20 kinds or grades of emery wheels made, none of them would, I think, be of any account for removing such propolis as we have here. I tried three different grades of them, and they were worse than worthless, if I may use such a term. If the glue was soft the wheels gummed up; if hard, the emery had but very little effect on it. I also made moulds, and cast a number of wheels out of different kinds of sand and cement; these were all worthless so far as removing propolis was concerned.

I next took a wooden roller about 2½ inches in diameter and set steel knives in it about ¼ of an inch apart, and had them project about 1/7 of an inch above the wood. These knives were pieces of thin sheet-steel, and were let into the wood by means of saw-kerfs, and fastened and held in place by cement. A disk of this kind, if made accurately, and hung so it revolves true, will, if run very fast, remove propolis from sections very rapidly. It never clogs up, even if the glue is so soft that it is difficult to clean the sections by hand, tho when the edges of a section are held against it, care has to be taken or the knives will catch on the corners and instantly tear the whole section to pieces.

I also made a perforated-tin disk, as described by a correspondent in the Bee Journal, and altho this would remove propolis quite rapidly, it was not nearly so effective as the knives. Tin being such a soft metal it soon wore down so smooth that it was of no account. Tho it is considerable work to perforate tin for this purpose by hand, it could no doubt be done very cheaply by machinery, but I feel sure that no really practical machine can be made to run by foot-power, that is, on the same principle as a sewing machine.

I tried sewing machines and a small turning-lathe, which was about the same thing, and there is not power enough to do effective work. I tried putting on a heavy balance-wheel, and while this was considerable help it fell far short of being enough so that practical work could be done. As probably all know, foot-power as applied to a sewing-machine treadle, is what its name implies—simply foot-power generated by the moving of one or both feet up and down. But there is another kind of foot-power that is obtained on a different principle, by the use of a long treadle that has a long sweep up and down, so that instead of being able to apply only actual foot-power the weight of the whole body can be brought to bear on the treadle. I saw and ran a large turning-lathe of this kind in a machine shop a short time ago, and I should judge that the power was about twice what could be obtained from a sewing-machine treadle, and more easily obtained at that, as nearly as I can tell from the picture of it. The Barnes' saw has this same kind of power, and if I am right in my estimate, that this kind of treadle gives double the power a sewing-machine treadle does, it will be ample to clean sections, and with power enough a disk or roller set with knives, as I have described, will clean at least three while one could be cleaned by hand; and the roller could be long enough so that one end could be covered with perforated tin, or something similar for cleaning the edges.

If I have a crop this season I shall give the matter another thoro trial, for when I have a crop the item of cleaning sections is no small one with me, for here 500 sections a day is more, on an average, than one person will clean. I have myself cleaned 600 a day. I have also worked just as hard on 400 a day—it depends upon the amount and kind of glue there is on them, and here the amount depends largely upon the character of the flow. If it is scant and irregular, much more propolis will be gathered than when the yield is free and regular. The kind of surplus arrangement also has some influence. Sections from T tins are harder to clean than those from section-holders. The bottoms of the former will be badly stuck up and soiled even

under favorable conditions, while the latter, no matter how adverse the conditions are, will have but two slight ridges of glue—one on each side of the insets.

As I am afraid practical machines for cleaning sections will not be in general use at least this season, for the benefit of beginners only I am going to say a few words about cleaning sections by hand, for I can remember the time when I could not clean nearly as many as I can now.

Most of those new to this work hold the section in one hand while cleaning it, and I even know a man who had produced tons of comb honey who said he knew no better way. It is, however, quicker and easier to clean a section if it rests on a solid bench, and if much of this work is to be done two benches of different heights, so that one can change off and work both standing up and sitting down, are a great help. On top of the bench tack a piece of board that is two or three inches wide, four or five long, and about $\frac{1}{6}$ of an inch thick. Have it back a few inches from the front of the bench. Stand the section on this strip so that the front projects over it a trifle, then scrape up and down, not across the top. The object of the thin board on top of the bench is to let the edge of the section project over it so that the knife can reach clear down. Of course, the same effect can be obtained by letting the section project over the edge of the bench itself, but if this is done there is nothing to catch or stop the downward strokes of the knife; and this makes it harder work for me. Some, tho, prefer to let the section project over the edge of the bench itself.

There is quite a knack about cleaning sections by resting them on a bench or table, but after it is acquired one can, if the sections are badly stuck up, clean at least a third more than by holding them loose in the left hand.

I prefer a knife the blade of which is stiff enough so that there is no spring in it whatever. Mine are made from small flat files: one edge is drawn down thin and sharp, and the other is left thick, and is ground square across; this edge is used mostly for cleaning the edges of the sections. The knives are long enough so they will reach clear across and clean the edges of two sides at once.

Southern Minnesota.

An Experience with a Queen and Nucleus.

BY EDWIN BEVINS.

I HAD an experience with a queen and nucleus last fall which was a little out of the ordinary, and which may be worth relating. Early in October I found a colony queenless, and resolved to re-queen by first giving the queen to a nucleus of hatching brood, and then gradually changing the frames of the colony to the hive of the nucleus.

Looking around among the colonies in the yard I found where the frames of brood could be easily gotten, and then sent for a queen. As there were evidences that a few bees had hatched from the combs, I did not fear any trouble, altho I thought it might be a little late in the season for such operations.

When the queen arrived I was so ill that I could hardly crawl from the house to the bee-yard, but as there was no one else around who knew what to do, I had to go. An assistant helped me to get the frames of brood and put them into another hive, and then I had him place the hive over the hive of the queenless bees, first putting a frame with wirecloth nailed to both sides between the two hives. Then I released the queen and escort by turning back one end of the wire covering of the cage. The cage was left on the wire covering of the frame close to the frames of brood. Then I crawled back to my bed.

About the third day after, feeling a little better, it occurred to me that I would better look after my queen and nucleus. I was not greatly surprised to find that no bees had hatched, but was surprised to find the queen in the cage instead of on the combs. I made her get there, and removed the cage from the hive, and then felt a little puzzled about what to do next. What I did do was to take the frame of wirecloth away, thus admitting the bees of the colony to the combs of the nucleus. I knew this would be all right for the brood, but did not know how it would be for the queen.

By this time I was used up, and again crawled back to my bed. It was two or three weeks before I could get out again, but the first thing I did was to find out what had become of my queen. I found the brood in the two frames of the upper story all hatched out as expected, and, looking

further, I found sealed brood in several frames of the lower story.

Ordinarily there is no risk in introducing queens on frames of hatching brood. What rendered it hazardous in this instance was the coolness of the weather which prevented the hatching of the brood.

A direct introduction of the queen to the queenless bees in the beginning *might* have been as successful, but I have had many losses by trying to introduce direct to the bees that have been for some time queenless. Probably the presence of the brood, and the fact that everything in both hives had become scented alike, helped to insure the queen a kindly reception.

Decatur Co., Iowa.

Holding the Breath While Handling Bees.

BY A. P. RAYMOND.

MOST bee-keepers, probably, have discovered that nothing is so offensive to bees, and so angers them, as a person's breath.

If any one doubts this he can easily convince himself by removing from a hive a comb covered with bees, and breathing upon them. I think just one trial will be sufficient to remove his doubts as to the truthfulness of the above assertion.

Very early in my experience in handling bees, I began and continued the practice of holding my breath while looking for queens upon a comb, or while peering into a hive for the same purpose—in fact, while performing any other difficult task that had a tendency to anger the bees. I thought I saw good results from doing this, consequently, as I said before, I continued the practice until it finally became to me "second nature," as it were. Whenever I was engaged in removing combs from or returning them to a hive, I would find myself unconsciously holding my breath, especially if the bees were inclined to be irritable. Of course, it would become necessary to breathe occasionally, but when doing so I would turn my head aside so the bees would not observe the least effects of my respiration. By first filling the lungs, a person may, after a little practice, hold the breath for nearly or quite half a minute without inconvenience.

My only reason for holding the breath while handling bees was simply to prevent angering them; but recently I came across the following item in the *Minneapolis Journal Almanac* for 1897, which, if true, sheds more light upon the subject, and, also, may be another explanation for the seeming good results I experienced from the practice. I have not as yet tested this theory as relating to stings, consequently I cannot vouch for its truthfulness, but I give below the article in its entirety for what it may be worth. I am unable to give the name of the author. Here it is:

JUST SIMPLY STOP BREATHING.

"It is a fact not generally known that if a person holds his breath wasps and bees may be handled with impunity. The skin practically becomes a coat of mail against which the insects vainly drive their stings. The moment a particle of air escapes from the lungs the stings will penetrate. In explanation of this curious fact, a well-known physician advances the theory that holding the breath partially closes the pores of the skin, and thus leaves no opening for attack. This interesting statement explains and enhances the value of a practice I have followed for the prevention of colds. For many years, my occupation took me to crowded political and labor meetings, generally held in rooms destitute of any means of ventilation. The heat was intense, the air fetid and poisonous. I have left such meetings bathed in perspiration and plunged into the chill air of a winter's night, thereby running the risk of catching the severest cold. Yet, strange to say, I enjoyed a singular immunity from such aggravating ailments. At the first touch of cold air I took a deep inspiration, and then held my breath for half a minute, in the meantime walking as fast as I could. During that half minute the pores of the skin were closed against the chilling atmosphere, and by the time the lungs called for reinvigoration, the body had considerably cooled, and the risk of a chill was over. I recommended the practice to public speakers, vocalists, entertainers, and those who are obliged to frequent unduly heated rooms. In my own case the practice never failed, and altho I fully believe in its value, I never understood the reason of it until a learned scientist came forward with the remarkable theory that while holding the breath the skin could be maintained impenetrable to the sting of a bee."

Holding the breath to avoid colds has been practiced, I think, by many persons with good results. What is nearly or quite as good, when emerging from an over-heated room into the cold, crisp atmosphere of winter, is to close the mouth for a few moments and breathe thru the nostrils, as the air thereby becomes partially warmed before coming in contact with the lungs.

If holding the breath is a sure preventive of bee-stings, every bee-keeper should be acquainted with the fact. Suppose you try it, this spring.

Clark Co., Wis.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Supplies Enough, Perhaps Transferring.

1. I have six 8-frame Langstroth hives, 1½ stories, complete with sections and starters. Five of the brood-frames in each hive have full sheets of foundation, and three have 3-inch starters. I have one colony of bees in an odd-sized hive, which I will transfer and make two colonies, on the Heddon plan. I will then have four empty hives. I will get first swarms in three of those (from a neighbor.) The question is, have I enough supplies for this summer? I have a good location for bees.

2. In transferring, can't I set the hive I want the bees in, over the old hive and drive them up into it, as well as to drive them into another box and empty them in front at the entrance?

3. Will there have to be queen-cells in the old hive before I transfer in order to make the second drive into another hive? IOWA.

ANSWERS.—1. In all probability you have supplies enough, unless it be for surplus, about which you say nothing. If the season be favorable, you ought to need some sections or extracting-supers.

2. That will be all right if your hives are constructed to make it convenient.

3. It isn't absolutely necessary, but you'll have better queens if started for swarming than you will have by forcing a weak colony to start cells.

How to Get Along Without Transferring.

I have six colonies of bees in common boxes, nailed all around. I am a beginner and know nothing about transferring. I am told by experienced bee-men that I will probably fail and sincerely regret it if I should attempt to transfer. The experienced bee-men are too busy with their bees to do it for me. I have three or four swarms that I caught the other day, in 10-frame Langstroth hives. If there is any way of making the old colonies help these new ones, or nuclei, swarms that I may form from the new ones, without getting the old ones out of their old hives, say for instance by changing stands, I should be very glad to have you tell me. I have one small new swarm. I thought to change places with it with one of the strong old colonies, but feared for the queen of the new swarm. CALIFORNIA.

ANSWER.—Some who do not care to transfer manage very profitably by keeping their colonies in box-hives as breeders. Wait till the bees in a box-hive swarm. Hive the swarm in a frame hive, setting it on the old stand and the old hive close beside it. In six or seven days remove the box-hive to a new place, at a time of day when the most bees are out. This will throw a large number of bees from the old hive into the new one, making the latter good for a big surplus. You may leave the old hive to breed up for winter, or you may drum out the remainder of the bees 21 days from the date of the first swarm.

Fears Foul Brood from Dead Brood.

In the first place, about Jan. 20, or a few days before, there was a warm spell here and a maple-sugar camp was opened, and the bees carried in some sap which caused the queens to lay from two to four frames of brood; then I believe the cold weather commenced on the 26th and continued until about Feb. 14, and that remarkable cold weather was during that time; a number of colonies were caught on one side of the hive when the brood was away from the honey. Each colony that died had from 15 to 30 pounds of honey. Now the question: This brood has been hung up and dried in the combs. Would you be afraid to use these combs to put into hives to hive swarms on, or to put in col-

onies now in place of combs that have drone-brood in them? Would you be afraid of foul brood?

You understand that so much is said pro and con about dead brood starting foul brood, by the bee-keepers of eminence, that it is hard for a man who never had a case of foul brood to understand what to do. Some claim dead brood will, and some say it cannot, start foul brood.

OHIO.

ANSWERS.—If I had such combs, I would most certainly use them, and would have no anxiety as to results. Whether it would be safe for every one is another question. In my case there is no foul brood in the vicinity, and has never been any. In a place where foul brood is more or less common, there would be danger that some of the colonies which died on these combs might have been infected, making it unsafe to use the combs. But if I thought there was no foul brood in those combs at the time the bees died on them, I wouldn't hesitate to use them. Even those who believe that foul brood may start spontaneously would hardly object to it, for you say the combs have been kept dry, and I think no one has ever claimed that foul brood could originate from dead brood unless it was moist and rotten. I've used hundreds of combs containing dead brood, and never had any harm from it.

Moving Bees a Few Rods—Feeding for Pollen—Candied Sections of Honey—Frames of Comb and Dead Brood.

1. I have 10 colonies of bees, wintered in the cellar. I took them out April 1. My bee-yard was full of snow, so I had to put them in the garden about four rods away. I will have to move them just as soon as I can hear from you. What time of day is best to move them, and what can I do to keep them from returning to the old stand?

I have been feeding them some corn-meal and sugar-syrup in a tin-pan—one-third sugar and two-thirds water. The 16 colonies will carry away three gallons a day. Can I give them too much of it?

3. I have some sections of candied honey that are not finished. What can I do with them?

4. I have some brood-frames of comb and some dead brood in them. Can I use them this summer? MINN.

ANSWERS.—1. It probably doesn't make much difference what time of day you move them. When you move them, take away all hives, stands, or anything that might make the place seem like home. After moving, set up boards in front of entrances, making it as troublesome as possible for the bees to get out, in hopes they will mark their entrances when they come out. If, in spite of all you do, some of the bees persist in going back to the old place, put a comb for them to cluster on, and in the evening give them to some colony that needs them.

2. There isn't much danger of feeding too much, altho you might look occasionally to see that too much of the imitation pollen is not stored. Of course it would not do to feed them so much of the syrup that the queen would be crowded.

3. Sprinkle with water, and let the bees eat them out.

4. Yes, but let the bees have them to take care of as soon as possible, by putting a hive full of the combs under a colony.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 50 cents; 50 for 70 cents; 100 for \$1.25; 250 for \$2.75; 500 for \$4.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

MAY 11, 1899.

NO. 19.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Booming and Fighting New Things.—Editor Hutchinson speaks of the tendency of editors of bee-papers to favor unreasonably and also to oppose unreasonably the adoption of new things. He says:

"The beginner in bee-keeping who reads Gleanings alone would be almost certain to send his order for plain sections and separators. If he read only the Progressive or the Canadian Bee Journal there would be little danger of his experimenting with them."

Mr. Hutchinson thinks fences and plain sections lead to a more perfect filling, but thinks it possible some better way may be discovered than to use fences. And yet, if the fences and plain sections do accomplish something not heretofore or otherwise attained, why not favor them until that "some better way" is "discovered?"

Railroad Rates to Philadelphia.—Secretary Mason, of the United States Bee-Keepers' Association, sent us the following for publication, bearing on the railroad rates to Philadelphia, in September:

STA. B, TOLEDO, OHIO, April 29, 1899.

EDITOR AMERICAN BEE JOURNAL:—I see on page 264 you quote from the Chicago Record of April 14, that railroad rates have been fixed for the Grand Army Encampment at Philadelphia, in September, and that the "rate of one fare for the round trip from Chicago and all points in the Central Passenger Association territory" has been fixed.

Just let me tell you and your readers what the "Com-

missioner of the Central Passenger Association" wrote me April 25—11 days later than the date of the Record. The Commissioner gives me the name and address of the commissioners of the different passenger associations, and adds:

"I am unable to advise you as to what reduced rates, if any, have been established by the associations named, on account of the Grand Army Encampment. The details respecting rates from this territory Central Passenger Association have not yet been definitely determined on, but it has been settled that a rate of one cent per mile short-line distance with a minimum of \$10 will be charged for round-trip tickets sold from this territory, going and returning by the same route. Tickets will also be sold at slightly higher rates which will carry stopover privileges and an opportunity to vary the routes on going and returning journeys; and if you will write us again in about a month we will probably be able to give you definite and complete information."

Now that is better authority than the Record, and I assure you I shall let the readers of the different bee-papers know what the rates are just as soon as I can find out myself, but any one can learn what the rate will be from their starting railroad point by asking their station agent, but it may be three months yet before the agents will get their instructions. I expect to know officially about it before they do.

If the other bee-papers will copy the above, or so much of it as they think best, it may help some to an idea of the probable cost.

Philadelphia is about 600 miles from Toledo, and one of our leading ticket agents told me this week, that a round-trip ticket from here will cost \$11.95. A. B. MASON.

Secretary United States Bee-Keepers' Association.

We supposed the Chicago Record had reliable authority upon which to base their statements, and it may be they are not so far wrong as they might be. At any rate, there is plenty of time yet to announce the rates, and all who will want to go will be able to find out definitely some time before the day they start. The important thing for bee-keepers to do is to begin now to arrange to be in Philadelphia Sept. 5, 6 and 7, when the annual convention of the United States Bee-Keepers' Association is held.

Thickness of No-Drip Cleats for Shipping-Cases.—

Editor Root is in trouble to know how thick to make them. First they were made $\frac{1}{4}$ inch thick. Then there was a clamor to have them thinner, and they were made $\frac{1}{8}$ thick. Now comes Byron Walker, a man who handles a great deal of honey produced by others, and says that the cleats should not be less than $\frac{3}{8}$ thick. If thinner than that, there will always be some cases with so much leaking that the leakage will fill up to the bottoms of the sections. Mr. Root rightly says that the thin cleat is all right if the comb is fastened in the section as it should be, but when partly filled and poorly attached it needs a thicker cleat to take care of the drip. Mr. Root, perhaps you'll have to go to the extra trouble of making $\frac{1}{8}$ cleats for the careful ones, and $\frac{3}{8}$ for the others. And yet there isn't much use in having two thicknesses.

A Foul Brood Law for Michigan is strongly urged by the Bee-Keepers' Review. Editor Hutchinson mentions what has been said about it in this journal, and urges every bee-keeper of the State to do all he can to urge the passage of the Bill. Altho bee-keepers of other States can do nothing to advance the passage of the Michigan Bill, they are personally interested in its passage, at least in every State that as yet has no foul brood law; for every State added to the list of those that have foul brood laws makes it easier to secure such laws in States not yet to the front.

"**Selling Honey by the Section** instead of by weight has been my usual method for several years. Most of the grocers accept this method very cheerfully, and, after experience with the plan, prefer it. Those who do not, generally like to buy by weight and sell by piece, because they are thereby enabled to squeeze out an extra profit. I use sections seven to the foot, with separators, of course, and they run very uniform in weight." So says J. A. Green, in Gleanings.

The Illinois Foul Brood Bill.—Secretary Jas. A. Stone, of the Illinois State Bee-Keepers' Association, desires us to publish the following statement regarding the effort recently put forth to secure a foul brood law in Illinois, but which unfortunately resulted in failure :

EDITOR AMERICAN BEE JOURNAL:—The Executive Committee of the Illinois State Bee-Keepers' Association desire in behalf of the Association to have kindly named all those who have assisted in an effort to secure a foul brood law for the State. We have found none more ready to assist than Editor York, of the American Bee Journal, and his letters to the House Appropriation Committee would have influenced a reasonable set of men, but we found the majority of that committee had no regard for reason, were not well enough brought up to give heed when our committee was being heard.

Mr. N. E. France, of Wisconsin, helpt us as far as was in his power, sending us pictures of apiaries destroyed by foul brood, and the hives all piled.

Mr. Dadant gave us letters of introduction to his senator, and the Bill was put in his (Senator Berry's) hands, and went thru the Senate booming—to be defeated by the Appropriation Committee of the House.

Mr. H. F. Moore, secretary of the Chicago Bee-Keepers' Association, did all he could to influence his representatives, as also did Mr. Jas. Poindexter, of Bloomington, but still we could do nothing with his representative—Funk. He insisted that the wild bees in the timber would hold the disease, and it would be useless to rid our apiaries of the disease as long as there were bee-trees in the timbers. Such flimsy arguments as this had their influence with the committee. And one of the committee-men said he was talking to one of his constituents who kept bees, and he told him he would not give a cent for such a law, as he never had foul brood in his apiary. These little things had their weight against us. But we had on that committee some of whom we are able to name: Chairman Curtis, Dr. Vincent, Messrs. Young, Rankin, and some others we are not able to name.

Among our enemies there were none more bitter than Stewart. He could not wait to hear from our committee, and moved (without the chairman giving heed) to report it back with the recommendation that it do not pass. Then there was another member that lookt at us as if he would say, "Just wait till I get a chance to swallow you!" We askt for a roll call, but were unable to get it. However, we will be able to get some of the names when we see their pictures.

J. O. SMITH, } Executive
JAS. A. STONE, } Committee.
CHAS. BECKER, }

We trust that whenever any of those who opposed the Foul Brood Bill come up for re-election they will be remembered by bee-keepers, at least, in a way that they will not soon forget. It seems strange that nearly every other organization except bee-keepers can get what they want at the hands of the legislature. But so long as self-seeking politicians are often elected to make the laws perhaps we ought not to be surprised that the dear people "get left." However, as the votes of the "dear people" put the selfish politicians into power, the place to do the hardest kicking is at home. 'Tis better to elect men of sense than those who are after only the cents instead of the best good of their constituents.

Philadelphia's "Old Honey-Man."—The Philadelphia Record says that one of the queer characters of that city, who goes on in his own quiet way, and who has wealth enough to afford him all kinds of luxury, if he so desired, is known by every man, woman and child in the southern part of the city as the "Old Honey-Man." The queerest characteristic possessd by this old fellow is his extreme reticence concerning himself and his past career. There are those who know that he was a sailor at one time, and, if he was not the captain of a ship, he was well up in the ranks. With a trayful of honey in the comb on his head, the old man traverses all the downtown streets and a few of the uptown ones, selling to all who care to buy. He has a list of regular customers among the old-timers, and his

visits to these are made with the regularity of a clock. For years the "Old Honey-Man" sold bananas and honey, and amast a fortune; but years ago he gave up bananas, and since that time devotes himself to dispensing honey and sweet smiles, for the old man is very genial.

MR. DOOLITTLE says [in American Bee-Keeper] a wooden paddle about 5x7 inches is the thing to kill cross bees that follow one around the yard. He once tried a paddle made of fine wire-cloth stretched over a wooden frame, something like a sieve. But he says he can hit a bee just as well with the solid paddle as with one that allows the air to pass thru. The latter sometimes only stuns the bee, while the solid one always kills it. Gleanings.

STENOG, who picks around among the neighboring fields of Gleanings, has this to say in reference to the word "alright" to which we called attention awhile ago :

"'Alright' is referred to as being possibly a new word. That's alwrong. Poor spellers often use it, supposing it follows the analogy of *already*. It is an eyesore to have such things thrust before us. But it is no worse than *sometime* as a word; as, 'He was here *sometime* ago.' *Sometimes* (an adverb) is always one word; but *some time* is an adjective and a noun. *Sometime* is obsolete. It used to mean *former* or *formerly*; as 'Monroe was *sometime* (once) president of this country.' Also *someone*, *noone*, and *anyone*, in place of *somebody*, *nobody*, and *anybody*, are gross blunders. If used they should be separate words."

We are agreed with Mr. Stenog on the word "alright," that it is "alwrong." But we wish he would unbend a little and pick up the reform in spelling which ourselves and others have undertaken. It wouldn't hurt him any to favor a little progress in this line, and some day he might be glad that he threw the weight of his influence on the right side.

MR. A. I. ROOT is always an interesting target at which Dr. Miller enjoys shooting off jokes. Fair samples of the "wads" in the Doctor's "popgun" are found in the following, which appeared in Gleanings for April 15 :

"My dear old Friend:—Please have my subscription extended. That's because I began with Vol. 1, No. 1 of Gleanings. I think it began not so very long after the first visit I made to you. That was not long after you had had a fire, in 1870, and had your jeweler shop and dwelling all under one roof. Other company was there, somewhat crowding the sleeping facilities; you and I slept together, and you kept me awake detailing a plan that was in your head for putting a hive under each hard-maple tree, tapping the tree, and having the sap run directly into the hive for the benefit of the bees. You didn't manufacture smokers then, and I showed you how to smoke bees with a pan of hot coals. You liked the plan, and as soon as I was out of sight you tried it and burnt up a hive, or tried to. I think I've slept with you a number of times since, and was distinctly the gainer on at least two separate occasions, when you absent-mindedly put your nightcap in my overcoat pocket instead of your own. I never lost anything by sleeping with you. I always put my Waterbury under my pillow. Please don't forget to have my subscription extended. "C. C. MILLER."

There's no telling what mischief those two "boys" will get into at the Philadelphia convention, next September. But they'll bear watching. I hope Pres. Whitcomb will keep both of his keen Nebraska eyes on them. If not, they'll make "Uncle Whit" more nervous than he usually is when joining in an Indian war dance.

The Premium offered on page 254 is well worth working for. Look at it.

A Plan for Watering Bees is given in the British Bee Journal that may be very convenient for those who drink much tea or keep few bees. The spent tea leaves are saturated with water and put in a saucer in a sunny spot for the bees.

Sacks to Contain Melting Combs. C. Davenport says, in the Bee-Keepers' Review, should not be of any woven cloth, as this will leave a large portion of the wax in the slumgum, but should be *coarse, knit, cotton* stuff, like that in a cheap, but heavy, coarse, knit, cotton sock.

Difference in Queens.—S. F. Miller had seven colonies of equal strength: one of them filled everything full from top to bottom, while the others gathered no honey to amount to anything. The editor of Gleanings thinks the difference in results might be accounted for by the difference in queens. He says:

"We once had a colony in our apiary that would fill its hive full of honey when the other bees would be almost on the verge of starvation. Work? We never had anything like them. Rob? They would clean out anything they could fight down. The queen of this colony we called the 'honey queen,' and her daughters were sold at advanced prices."

Putting Section-Supers Between Stories of Brood-Combs, is advised in the Progressive Bee-Keeper, by R. C. Aikin, as a sure way of getting rushing work done in the sections. G. M. Doolittle says, in the same paper, that it is good practice to have an extracting-super between two stories of brood-combs, but it's a bad thing for sections, because the old, black comb from above will be carried down in bits to help seal the sections. Even with old combs be-

low, the snow-white appearance of the sections will be affected. "To produce the most 'snow-white' honey in sections, it must be built over *new combs* below, or over combs of *sealed brood or honey* by *very strong* colonies."

Spring Feeding of Bees is discussed in Gleanings by G. M. Doolittle. He objects to outside feeding, because bees for two miles around must be fed, because there is some danger it may start robbing, and because those which need the least may get the most. If a warm morning is followed by a chilly afternoon, bees may be lost by flying out, and at this time of the year one bee is worth as much as a hundred at the close of harvest. In early spring each colony should have from 10 to 15 pounds of honey, then they will need no further feeding unless the weather is bad in fruit-bloom. Instead of feeding nightly for stimulative purposes, he thinks it better to give full combs of honey, and if these are not at hand, then combs filled with sugar syrup.

Starting Bees in Sections.—The editor of Gleanings commends a plan for starting bees in sections given by Mrs. A. J. Barber. She says:

"I had 60 colonies of Italians in my out-apiary, and in trying my experiment I tried to be fair. I took 30 supers of half-depth extracting-frames full of comb from the home apiary, and put them on 30 hives in the out-apiary at the same time that I put sections on the other 30 hives. In four or five days the extracting-combs were full of new honey, and the bees excited and busy at their work, while most of those having sections were loafing, and some had swarmed. I raised the combs by putting a super of sections between them and the brood-nest. At the end of two weeks from putting on the combs those sections under the combs were better filled than those on the hives that had no combs. As soon as the combs were sealed I put them away to extract, having that amount of honey extra, and the bees started nicely in their work. I had only about a third as many swarms from those hives as from the ones with sections and no combs."

But those who have been in the habit of using bait sections will probably think it is no advantage to use extracting-combs in their place, unless it be desired to have extracted honey.

THE G. B. LEWIS CO'S BEE-HIVES AND SECTIONS

ARE MODELS OF PERFECTION.

This is the Verdict of Thousands of Customers and the Acknowledgment of Competitors.

Our unrivaled facilities, coupled with twenty-five years of manufacturing experience, enable us to anticipate and supply every want and need of the bee-keeper, promptly and accurately.

GENERAL ITEMS

Bees in Splendid Condition.

My bees were removed from the cellar April 11 and 13, and are in splendid condition. I placed 110 colonies in the cellar Nov. 20, and they were there nearly five months. They wintered with a loss of two colonies.

I left 14 colonies on the summer stands, one of which died. Bees which were left on the summer stands in this vicinity have suffered a terrible loss. G. F. TUBBS.

McKean Co., Pa., April 22.

Bees Doing Well on Mesquite.

The information contained in the report of the Colorado convention in the Bee Journal was worth many times the subscription price, to practical bee-keepers who are trying to make a living from the business.

I have only 110 colonies at this date. We had a very dry fall, winter and spring—no rain since October. Swarming is some four or five weeks later than usual. However, my bees have been doing well the last week, gathering honey fast from the stable honey source of this dry region—mesquite—which is in full bloom now.

J. J. K. FITZPATRICK,
Dimmit Co., Tex., April 15.

Average 75 Percent Loss.

I lost 21 colonies out of 25; but I will not give up. Some of my neighbors have lost all. On an average the loss will be about 75 percent. C. L. HAMILTON.

Nez Perces Co., Idaho, April 29.

Last Season a Poor One.

Loss in bees in this section is heavy, owing to long, cold winter. Last season was a poor one, as it was very dry, and the grasshoppers ate most of the bloom of the second crop of alfalfa and sweet clover.

Mesa Co., Colo., May 1.
I. E. PALMER.

Fully Half of the Bees Lost.

Most of the bees in this section of country are now out of the cellar, and a large number of reports have been received, saying that as nearly as can be ascertained fully 50 percent of the bees died. I lost 100 colonies out of 261. Some of the smaller apiaries are entirely swept away. Just to-day I received notice from a prominent bee-keeper that has lost 100 colonies out of 140. Diarrhea did the work here.

AUGUST BARTZ,
Chippewa Co., Wis., April 18.

Bees Had a Severe Time.

Bees have had a severe time this spring, all old bees dying off in the cold weather in February, leaving the hives full of brood and young bees, and no honey coming in caused a cessation of brood-rearing, which has been disastrous to the early honey-flow. However, we have some very fine honey from tupelo. Next comes holly.

CORNELIUS L. RICE,
Vermillion Co., La., April 15.

A Laying-Worker Experience.

I am just making a start in the bee-business. I have three colonies that I wintered, and if it had not been for the book "A B C of Bee-Culture," I would be minus one colony soon. It was like this: In going over my bees not long since I found the brood to be all drones in one hive, and of course I got my bee-book and lookt it up.

and found the colony had a laying worker and no queen. I procured a queen, put her in a hive, placed it where the drone-hive was, removed Mrs. Laying Worker and her drones to one side, and now they are doing nicely. The bees all left the old hive but 10. I thought this pretty good.
 There are very few bees in this part of the world.
 A. C. SMITH.
 Columbia Co., Wash., April 16.

Just Rolling in the Honey.

Bees have been just rolling the honey in since April 15. We had fine rains all thru this country, so much so that I had an apiary of 85 colonies completely washed away from a place where the water was never known to run before. I will devote most of my energies to restocking for a while now.
 GEO. W. HUFSTEDLER.
 Bee Co., Tex., April 23.

Heavy Losses of Bees.

About 90 percent of the bees are dead. Honey-dew is thought to have killed them. Much of the honey has a bad taste. One man put 51 colonies into the cellar and lost all; another lost 4 out of 80; and a lady had 18 colonies last fall and lost all but one.
 I learned much last season from the American Bee Journal, and had hoped for a prosperous season in 1899.
 A. J. CUSHING.
 St. Croix Co., Wis., April 25.

Quite Heavy Winter Losses.

I see by the reports that the winter losses of bees were severe the past winter. In this locality the losses have been quite heavy. One man reports 75 percent loss (but I suppose he is excusable, as he says he can't learn anything by taking a bee-paper—knows too much. See ?). But the bees that were packed wintered fairly well.
 WM. BROVYN.
 Weld Co., Colo., April 23.

Wintered Fairly Well.

Our apiary at home wintered fairly well, better than I expected, and most of the bees are in good shape; they are working hard on willow now. Some of my neighbors lost 50 percent, others all they had. I think long confinement and dampness was mostly the cause. What few are left will need careful watching to bring any good results.

Last year my sales of comb honey amounted to \$100, besides the extracted. I run 20 colonies for the latter. My best colony stored 200 one-pound sections of comb honey, mostly white clover.

The American Bee Journal comes as regularly as day and night. It is just like all other good things—the more you read it the better you like it. I would not do without it.
 R. H. NORTMAN.
 Jackson Co., Wis., April 24.

Clovers in Bad Shape.

As nearly as I can find out, of those bees that were left out-of-doors 90 percent are dead; of those in the cellar, 25 percent are dead. Starvation, poor stores, and diarrhea were the causes of those dying in the cellar; very cold, long continued, and starvation, were the causes of the loss out-of-doors. Clovers are in bad shape. The season is at least three weeks behind. Elm is in bloom, and cottonwood and box-elder will soon follow.
 E. C. WHEELER.
 Marshall Co., Iowa, April 23.

Agreeably Surprised in Wintering.

I took my bees out of the cellar April 4, after a confinement of 138 days, the longest time I ever had bees confined. I had begun to lose hope in them, but I was agreeably surprised. They had daubed their hives somewhat, but most of them were booming with bees, and the queens had commenced

to lay. They were pretty short of honey. I have been feeding them nearly every day since, giving them C sugar, and oats and corn ground for pollen. I tried them with buckwheat flour but they seemed to prefer the oats and corn. **J. C. ARMSTRONG,**
Marshall Co., Iowa, April 18.

Satisfied with the Results.

Last year was my first experience with bees, and I did pretty well, thanks to the American Bee Journal. I got 33 pound of surplus from the old colony, 19 pounds from the new colony, and a number of unfinished sections. I think the honey-flow was cut off by dry weather, but I am not looking for so much surplus as some get that I read about in the Bee Journal. I was surprised at what I got last year, and I think by better management I can make them average that one year with another. I now have four colonies in good shape, having lost one in wintering. **LEWIS LAMKIN,**
Woodbury Co., Iowa, April 29.

Lost None in Wintering.

I have about all the live bees in this part of the country. The rest wouldn't read, and lost all. Mine are all alive and strong with brood in four frames to-day. I wintered them in the cellar. The Bee Journal is my guide, and will be. **J. P. BLUNCK,**
Webster Co., Iowa, April 28.

Working on Maple and Apple Bloom

Busy. Great rush of the season. Don't think I ever saw bees at work on maple bloom and apple bloom *simultaneously* before. Usually weeks apart. **E. E. HASTY,**
Lucas Co., Ohio, May 1.

No Spring at Dr. Miller's.

It's summer. Was no spring. Jump right square from winter into summer. Apples in bloom May 2; earlier than 1897 or 1898. April 29 the mercury stood at 91°! **McHenry Co., Ill., May 2. C. C. MILLER.**

Good Honey Crop Expected.

We are having weather that suits the most exacting agriculturist; glorious showers have been falling for the past three days. They are light and will do immense good. I have no particulars from the South. The honey crop here gives evidence of being good, tho it may not be as heavy as I could desire. **W. A. PRYAL,**
Alameda Co., Calif., April 15.

Succeeding Well.

This is getting to be quite a bee-country. I commenced keeping bees last spring, and am succeeding well—all on account of the American Bee Journal, which I could not do without. **H. T. WILSON,**
Rice Co., Kan., April 29.

Bees Doing Well.

Bees are doing well now, storing honey from the "sugar-bush."
SYLVESTER PEASLEY,
McLean Co., Ill., April 27.

Severe Loss in Wintering.

Under the above heading, Mr. H. W. Dudley says, on page 251, that about 50 percent of the bees in Salt Lake County and other localities have died the past winter; and that Pres. Lovejoy has lost all but four colonies. This should have read "all but four in the home apiary." Otherwise Mr. D. is very nearly right. Some have lost from 60 to 90 percent, while others have not lost 10 percent. Salt Lake County cannot be considered a bee-keepers' paradise. The wintering question seems to be the hardest problem. I never try to winter more than 10 to 12 colonies at the home apiary, and 1

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |

usually lose about half of them, no matter how I fix them; while with the same treatment I obtain much better results elsewhere. I think the evidence is pretty conclusive that smelter smoke is the principal cause of loss, because at and near the smelters no bees live thru the winter.

We are having beautiful weather here, now; the hum of the busy bee is heard on all sides, the trees are in bloom, and all nature looks bright. The health of the people is improving, and all are hopeful for nature's stores in abundance. E. S. LOVESY, Salt Lake Co., Utah, April 28.

A Leader with Poultry and Bees.

I have a friend that sells a little over \$2000 worth of honey each year from 200 colonies of bees. Can any of your readers beat that? If they can I would like to hear from them. I also have a friend in the chicken-raising and egg business, and he tells me for some time back he has been getting 120 dozen eggs weekly from 300 hens. Can anyone beat that? G. T. JONES, Sutter Co., Calif., April 26.

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of **Bee-Keepers' Supplies**,

They have also one of the **LARGEST FACTORIES** and the latest and most improved machinery for the manufacture of **Bee-Hives, Sections, &c.**, that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip't with best machinery, all combine to enable this firm to furnish the **BEST GOODS AT THE LOWEST PRICES.**

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

This is a good time to send in your Beeswax. We are paying **26 cents a pound—CASH**—upon its receipt.

Small Loss in Wintering.

The Bee Journal is just the paper for beekeepers. I have 13 colonies doing nicely. I lost only one colony during the winter. They were on the summer bench with only a roof and the back closed, front open, and 18° below zero for a week in February.

J. W. McFADDEN, Nez Perces Co., Idaho, April 27.

Extractor for Shallow Frames.

I notice Dr. Miller asks for somebody who has had experience to answer Iowa's question about what kind of extractor to use for 5 1/2-inch frames, on page 247. This is just the size of my extracting-frames, and I use the No. 17 Cowan extractor. The comb-baskets are 11 1/2 inches inside, so there is plenty of room for two frames. I use thin super foundation for shallow frames, and it is all right without wiring. I have 1,000 of these frames built with thin super foundation and no wire.

I think 75 percent of the bees owned by farmers in this vicinity are dead. My loss was 18 percent. Honey-dew was the cause of my loss. I think. H. H. PORTER, Sauk Co., Wis., April 29.

Fruit-Bloom Sprayed Ignorantly.

We lost bees heavily just at apple-bloom time, and I know that our farmers spray their trees that I want to warn them not to spray while apple-trees are in bloom. I do not know that they do, but I am almost certain one or more seasons they did spray in apple-bloom, for those seasons there were scarcely bees enough left in the hives to take care of the brood, when at the very first day our trees bloomed our bees were strong, and in three or four days were very weak in numbers. Of course, no one who knew it would kill bees would do so; it is done in ignorance.

Our bees flew strong in February, but now are much depopulated, and quite a number wintered out-of-doors are dead—just simply died out.

The severe winter was very hard on our peach-trees. We are obliged to replace many. We had a nice little orchard of about 1,600 trees, about 1/2 or more old enough to bear. We had some 400 bushels from them last year, of very fine, large freestones, lasting about three months.

Mrs. L. C. AXTELL, Warren Co., Ill., April 23.

PRICES OF Bingham Perfect Bee-Smokers AND HONEY-KNIVES.

| | |

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, April 18.—Best grades of white, 13c; off in color, etc., 11c@12c; light amber, 10c@11c; dark amber and mixt buckwheat, 7c@9c. Extracted, clover, 8c; other grades of white, 7c@7 1/2c; ambers and dark, 6c@7c. Beeswax, 27c.

Sales are in a small way, as the time of year is with us which usually sees the close of active sales. Owing to the inclement weather which has cut off the early fruits and vegetables the honey market has benefited, so that all of the white comb is nearly disposed of. There is quite a quantity of dark and undesirable comb being offered.
R. A. BURNETT & Co.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10c@11c; dark and amber, 8c@9c. Extracted in fair demand without change in price. Beeswax, 25c@26 1/2c.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey.
M. H. HUNT.

NEW YORK, April 19.—Fancy white, 12c; No. 1 white, 10c@11c; amber, 9c; buckwheat, 7c@7 1/2c. Extracted in good demand at unchanged prices. Beeswax quiet at 27c.

Our market is well cleaned up on comb honey. There is a fair demand, especially for white.
HILDRETH BROS. & SEGELKEN.

SAN FRANCISCO, April 2c.—White comb, 10c@10 1/2c; amber, 7 1/2c@9c. Extracted, white, 7 1/2c@7 3/4c; light amber, 6 1/2c@7c. Beeswax, 26 1/2c@27c.

Light supplies of both comb and extracted operate against any special movement in honey. Prices remain notably as before. New crop honey will be on market in about 30 days, but the yield is certain to prove light, and there will be very little white sage, which is the best grown.

BOSTON, April 18.—Fancy white, 13c; No. 1, 11c@12c; A No. 1, 10c@11c; light amber, 9c. Extracted, stocks about cleaned up. Nominal price for white, 8c; for light amber, 7c. Beeswax, very light stocks; selling at 27c@28c.

Naturally the demand for honey is gradually growing less, and altho stocks on hand are not large, still the demand is so small that the general feeling is weak and prices are being shaded in order to work off stocks.
BLAKE, SCOTT & LEE.

KANSAS CITY, April 6. Fancy white comb honey continues in good demand at 13 1/2c@14c; choice white at 12 1/2c@13c; dark, 10 1/2c@11 1/2c. Extracted scarce at 6 1/2c.
PEYCKE BROS.

CLEVELAND, March 9.—Fancy white, 13c@14c; No. 1 white, 12c@13c; A No. 1 amber, 10c@11c; No. 2 amber, 9c@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.
A. B. WILLIAMS & Co.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11c@12c; some very poor selling at 6c@7c, and dull. No more business in honey before the opening of the ensuing season.
BATTERSON & Co.

OMAHA, April 18.—There is but little stock left in dealers' hands now, and realizing that no further receipts can be expected until another crop gets into the market, it is held firm at 14c for fancy white comb. Extracted, 7 1/2c.
PEYCKE BROS.

Nuclei of Bees For Sale.

We have arranged with a bee-keeper in Lee Co., Ill., about 100 miles west of Chicago, Ill., to fill orders for 3-frame (Langstroth) Nuclei of Italian Bees, with Queens, in light shipping-boxes, at \$2.75 each, or in lots of 5 Nuclei, with Queens, at \$2.50 each. Address,

AMERICAN BEE JOURNAL
 ESTABLISHED IN 1861 OLDEST BEE-PAPER IN AMERICA
 DEVOTED EXCLUSIVELY TO THE INTERESTS OF HONEY-PRODUCERS

39th YEAR.

CHICAGO, ILL., MAY 18, 1899.

No. 20.

CONTRIBUTED ARTICLES

Agave Americana, or Century Plant.

BY W. A. PRYAL.

A HONEY-PRODUCING plant should yield a crop of honey every year after it has once reached its period of blooming. Then it should not be one that the bee-keeper should have to wait a century before he sees it yield its crop of honey. I am afraid there are very few apiarists in this world that would care to plant for a crop for nectar that they would be likely to harvest when they were ready to be gathered themselves in that vast crop that death stores away each year with more or less pains. Of course, no one knows a bee-keeper who ever sowed the seed of a plant that he had to wait a century before his bees gathered honey from the blossoms of said plants.

Herewith is presented a very nice picture of a century plant. Who has not heard of this plant? Those who have not seen it, have come to believe that it is a wonderful part of the vegetable creation. It may be, but I have never looked upon it with so much wonderment. Perhaps this is owing mainly to the fact that I have been familiar with it almost as long as I can remember. Still, there are a few features about this plant that takes it out of the ordinary run of plants we are wont to meet in our daily intercourse with plant-life. In warm climates it makes a rapid growth, that is, it seems rapid, for its leaves become quite long and succulent, and sometimes numerous. They are great, lubberly-looking leaves, and remind one for all the world of whale-bone just as it is brought from off the whaling ships, tho they are of a greenish-gray color, and their edges barbed with vicious hooks or thorns that are curved toward the trunk of the plant, thus being able to catch or wound anything that comes within their reach. Then, the end of the leaf has a sharp-pointed spike or thorn that is so hard that a keen-edged knife will cut it only with difficulty. I have heard that in some places butcher-birds impale their prey on these points, and often every leaf will have its end "ornamented" with a

grasshopper, butterfly, or some other insect. * * * But I am to tell of the plant as a honey-producer. In doing this let it be understood that I am not going to advocate the planting of agaves by the apiarist as an addition to his bee-flora. Should he live in a climate as mild or warmer than that of California, he may set out a few for ornament or curiosity, or both. In time, and it won't be a century, as many have been led to suppose by the misnaming of the plant, it will bloom and he will see his bees swarm on the flowers as he never before saw bees crowd upon a flower to extract the nectar therefrom.

For years I had noticed bees working upon these flowers, but as the flowers were always so high from the ground, I did not have a chance until a year ago of observing the amount of nectar a single flower yielded. In from 8 to 12 years one of these plants will begin to show signs of getting ready to flower. After blooming the plant dies, tho it has made provision for continuing its species by numerous suckers. Its asparagus-like stem or scape will then push its way from out the sheathing of the last leaves the original plant will produce, and rapidly rear its tip skyward. Tho I have never measured a day's growth of one of these trunks, I verily do believe that it is no uncommon thing for them to grow over a foot in 24 hours. In a few weeks the plant will present the appearance of the one in the engraving shown here, and possibly be 25, or 30 feet tall.

It was while one of these trunks was making giant strides upward on our place, that its weight was carried out of the perpendicular, and its roots were unable to hold it upright, so it came toppling to the earth. Yet, while the main portion of the trunk remained in a recumbent position, the portion that was to bear the flowers raised itself erect. Thus I was enabled to study the flowers at close range. It was delightful to see bees pile over each other to get at the nectar. And such quantities of the fluid! I never saw anything like it before, nor do I expect to again, unless I look into more flowers of the century plant.

The flowers are anything but pretty; they are of a nasty yellow color; a half-inch or more across, and about one-and-a-half inches deep, sometimes more. They always maintain a vertical position, so that the nectar does not run out of the flower-chalice. I was able to make a photograph of a cluster of the flowers. With a glass syringe, such as is used to charge a fountain-pen, I have taken sufficient nectar from three or four flowers to fill a dram-phil: this at one time.

The nectar was as clear as water. I set a small bottle of it in my room. In a few days thereafter, on examining it, I

found that fermentation had set in and the cork was forced out. Talk about rank odors! I suppose there are worse smells in this world, but I have fortunately not come across them, nor I don't want to, either. I hardly think the honey the bees would be able to store from these flowers would be like the odor I have mentioned, as the bees would put the nectar through a process that might rob it of its objectionable features. Above I said I did not see anything wonderful about this plant. I must make an exception: it is the odor of its nectar. This peculiar smell is noticeable, to some extent, in the flowers.

The Agave, or Century Plant, as it is commonly and improperly called, is a native of Mexico and South American countries. By some it is referred to as the American Aloe. This is incorrect. There are several varieties of the plant, one of which, I believe, is a native of California. In South America the natives make a kind of cordage from the leaves. In Mexico juice obtained from the leaves is fermented and made into a drink which is said to be agreeable, tho intoxicating. I should think if this drink was as odoriferous as I have found the fermented nectar to be, a man would have to have a strong stomach to tackle it—one for instance that could delight in storing away Limburger cheese.

Dr. Miller Pitch Into About Pure Italians, Five-Banders and Albino Bees.

BY G. M. DOOLITTLE.

FOR several years Gleanings kept an arena for Dr. Miller and Doolittle to fight in, and it seemed to do Editor Ernest Root lots of good to see Miller and Doolittle "lock horns" therein. But our Editor York is such a peacemaker that he would not allow of any fighting anywhere about him, so it will be of no use to call on him to open up an arena for any one. Nevertheless, I am going to pitch into the good Doctor "just a wee little bit" to see what the result will be. As Dr. Gallup used to say in these columns, that he, when a boy, would hit the "old tom-cat between the eyes just to see what effect it would have." And so he would hit Flanagan, Quinby and others, and the effect was something which brought lots of practical things out in the good old American Bee Journal. With this introduction finish, I now call on Dr. Miller to stand up and defend himself.

You say on page 198, in reply to "Johnny Bull," "The original pure Italians that came from Italy were three-banded, that is, the first three bands of the abdomen next the thorax were yellow." Now, Doctor, did you ever see any pure Italians that came from Italy? If so, in what sense do you use the word "pure"? If you use it in the sense of "free from mixture," as the Standard Dictionary speaks of purity, how did it come about that bees were bred from this original pure stock having "all the bands yellow," as you speak of in describing the golden Italians?

Then, Doctor, did you ever see an Italian *bee* which came from Italy, except a queen? If so, were the first three bands (?) next the thorax yellow? And did you ever see even *one* bee from an imported queen that had three yellow bands?

But what do you mean by bands? You saw that question-mark back there, did you not? That doesn't mean "sic," exactly; but I had supposed the yellow was on the horny segments of the abdomen. In other words, I had supposed that the abdomen of each bee was composed of six horny segments, instead of six "bands of the abdomen," as you put it, or would have, had you spoken of the six instead of the three.

Now, if "bands," as you used it, meant segments, did you ever see *one* single bee from an imported queen that had three yellow segments? If so, you have seen something that I never saw. In the first place, I never saw a single worker-bee from an imported queen that had any yellow on it at all. The color was always a maroon, chestnut or leather color, not yellow.

In the next place, I never saw a single bee from an imported queen that had three segments which were all of a maroon color. Did you? Was not each of the three segments next the thorax composed of both maroon color and black or dark brown, and did not these stripes of maroon color and black, running around the top part of the segment, constitute the bands? Then as these pure (?) maroon-banded bees were bred in this country, did not the color of maroon become changed to orange yellow, so that

we had the American Italian bee with three yellow bands on the first three segments of the abdomen?

Don't sit down yet, Doctor, for I want to hit you some more. You further tell "Johnny Bull" that "breeders in this country by selection have secured workers with five yellow bands." Now, did you ever see a single worker-bee that had both yellow and black (thus making bands) on five of the segments of the abdomen? If you have, you have seen something which I never did. I have seen workers with both yellow and black on four segments, but when it came to pass that a yellow and black band was found on the fifth segment, some of the other segments lost the black entirely, so that a part of the segments (usually the first two, three or four next the thorax) were a solid yellow, thus making the worker appear like "a lump of gold" when out sporting at the entrance for its "first play-spell" in the sunshine.

Next you tell "Johnny Bull" that "breeders in this country by selection have secured workers, . . . some having all the bands yellow, these last being called golden." Now, Doctor, look out, I'm going to hit you hard, right straight between the eyes. Did you ever see a single worker-bee having all the bands (segments) yellow? If so, I stand ready to give you ten dollars for the mother of that bee. There, I knew that \$10 would hit you hard, for I see you are down. "Ten dollars lost!" did I hear you exclaim? Not so. You can never lose something you never had. See?

But I am not thru with you yet, even if you are down. You tell "Johnny Bull" that "albinos among bees are much the same as albinos among the human race—bees which have been so bred that the coloring-matter is somewhat lacking." Did you ever see an albino bee? If so, what part of it lacked in coloring-matter—the head, thorax or abdomen? Was the coloring of the horny segments of the abdomen so lacking that the yellow or maroon part of the bands were white? The Students' Standard Dictionary says albino means "a person, animal or plant unnaturally white; a person with milky-white skin and hair, and pink or red eyes." And as you "swear" by the Standard Dictionary, and tell us that "albinos among bees are much the same as albinos among the human race," of course we shall all be looking for a bee whose head, thorax and abdomen are milky-white, all but the eyes, which should be either pink or red. Now, Doctor, doubly look out, for I'll give you twenty dollars for the mother of such a worker-bee as that.

Remember, I am going to leave you now, lying there under that pile of thirty dollars till you reflect a little while, and tell us what you really meant by those answers to "Johnny Bull," but I have "another grist" for you from the same number of the American Bee Journal, and would "go for you" still further, but I always considered it mean to trample on a man after he was down.

(Aside to the reader.) I have purchased several albino queens, and all the difference I could see between their workers and those of the ordinary Italians was, that the majority of the workers had white or gray hairs on them instead of the yellow or dark-brown hairs of the Italians.

The Laying of Young Queens—Queen-Rearing.

BY HENRY ALLEY.

SOME time the past winter I read a quotation in this paper that was decidedly wrong, and I have been expecting to see it denied by some of the old correspondents. As no one has done so, I am moved to say something about it.

The quotation was taken from a foreign bee-publication, and the wrong statement was by a foreign bee-keeper who, it seems to me, must be a person of limited experience in queen-rearing, to say the least. The writer said something like this:

"Young queens never lay their eggs compactly as old queens do, but scatter them over the combs." Such a statement is as far from the truth as any statement can be. The best evidence that a young queen is of no value, or an old queen, as for that, is the fact that she does not lay her eggs compactly. If she "skips" even a few cells, she is not up to the standard I place upon all queens.

When a queen scatters her eggs, pinch her head—she has lost her usefulness. The queen that deposits an egg in every cell, and every egg alike, is the queen for me, and shows every indication of being well-bred, and of the first quality.

While I admire large queens, I must say that the best, most prolific and profitable queens I ever had were medium in size. On the other hand, the meanest queens I ever saw were very large, and were reared from cells taken from a colony that had cast a swarm. I do believe, and have always claimed, that the best queens we have are reared by artificial methods. I certainly have found this correct in my own experience.

Some one has said that any one can rear queens. That is correct. But every one who rears queens cannot produce all good queens. I know I cannot, and I have been trying it for 37 years. Nor do I believe every one who rears queens can become expert at the business, any more than all can become expert at any kind of business. There are but few people of the many in any kind of business who can become expert at it. I know that the person who rears queen-bees must use his brains a good deal if he produces a good queen by any method known to bee-keepers. Many have found this out, and have retired from the business.

There is no part of the bee-business that does not require tact, brains and long experience in order to become an expert and to be successful. A bee-keeper may be located in a land of honey, but he never can get that honey stored by bees unless he knows how to do it. One must use his wits and his muscle, and then a mark can be made in this world. I suppose we are on this earth for some good purpose, and the only way to do to advertise our existence is to put a little kick and push into business, then if there is not much money in it there may be a little fame, and that may help out some day.

The Honey Season in California—Other Items.

BY PROF. A. J. COOK.

AS is well known, California has two markt peculiarities as a honey-producing State. First, the immense crops of honey in certain years; and, second, the numerous years when no honey is produced at all, or at least little more than enough to keep the bees. Since I came to the State, in 1894, each alternate year has been visited with a drouth, and no honey was produced at all. The other years have not only produced honey, but the crops have been enormous. The fact that drouth is surely followed with a dearth of nectar-secretion is so well understood that if we get very much below the average rainfall the bee-keepers themselves are entirely despondent, and count on no crop at all.

The present season bids fair to bring two seasons of no honey-production in succession. It has generally been thought here in this region that 15 inches of rain—which is about our average—was necessary for a crop of honey. Anything below that would result in a diminisht crop, and, if very much below, no crop at all. Last year the flow of rain was just about one-half the average, and except for a short time in early spring, very little honey was stored. The rainfall the present season—unless we get little more—is hardly up to that of last. Yet I think we cannot judge correctly of the present year from our experience of a year ago. The present season all the rains that have come have been when most needed, and have come in such gentle mood that every drop has been utilized. It is certain that the grain crop this year about here will be much better than that of last year. It is possible that nectar-secretion will also be different.

The first year I came to California—1894—we had a small rainfall, which was well distributed thru the season. I taught the botany that year, and was a close student of the flora. There was a well-markt and continuous succession of flowers from the early spring-beauty, as I should call it—*Gilia dianthoides*—to the host of composite flowers which appeared from July on. From my study since I judge the succession that year was well-nigh typical. The three following years, one of drouth and two of good rain supply, showed a succession of flowers much the same as that of 1894.

Last year, 1898, the early spring was exceedingly dry. The flowers came very early and in scant numbers. I despaired having enough for class use; but in early April, as my work commenced, a copious rain came with it, and I found that the early flowers came again, and so with a little more trouble to visit the canyons we had no difficulty in finding all the flowers we needed for our class use; indeed, the range in number quite equaled that of any previous year.

This year we have a season much different from any of

the previous ones. The flowers seem to be buncht, the early ones coming late, and the late ones coming forth early. The beautiful *Gilia*, already mentioned, and the shooting-stars, are fully a month later than in any of the previous years, while the black sage is in full bloom for weeks before its usual time. These show that this season is quite different from any that we have had before. Is it possible, then, to correctly judge of what the season may bring forth in the way of growth, vigor, and may we not add, nectar-secretion?

While I fear that the bee-keepers will be disappointed again this year in not securing a crop in this region, I am not at all sure that such will be the case. I find the bees now busy on the black sage and the just-opening white sage, as well as on many other flowers, and so far as I can judge they seem to be getting not a little honey. A week ago I met on the streets of Los Angeles our friend Mr. J. H. Martin, and found him quite hopeful of the honey crop the present season. I think that most bee-keepers would not sympathize with him in this feeling.

Several of the largest apiarists of Ventura County have moved their bees to the region of the alfalfa fields in the San Joaquin valley. They expect, and not without reason, not only to get enough honey to sustain the bees, but also hope for some surplus besides. It seems more than likely that this is a very wise course, and yet, if we should have a partial crop here it might pay better to keep the bees at home, as the expense of moving is by no means a trifle.

NATURE AND SOURCE OF HONEY-DEW.

I have been very much interested to read the various comments upon my article in a late number of the *American Bee Journal* regarding the nature and source of honey-dew. There seems to be not a little testimony that honey-dew may come at times as a secretion from the plant. Yet there seems to be almost as much that it rains down a product from the heavens. This latter seems so improbable that I think almost any student of nature would hesitate to give it credence, except as he had most crucial and repeated proof.

I should be very glad to receive samples illustrating honey-secretion from plants. One writer in the last *Bee Journal* is very certain that bees do not gather honey-dew secreted by insects. There is no doubt at all in this matter. I have known bees to gather large quantities of honey both from plant-lice and scale insects. The former was of excellent quality, and would rank first-class both as to color and flavor in any market.

Honey-dew from the large plant-louse in Michigan, and from the coxcomb-elm plant-louse, both furnish material for excellent honey. I have repeatedly found the nectar so abundant in the last case that I have been able to take it first hand directly from the insect, without waiting for the bees, and with others pronounced it of most excellent quality. On the other hand, the honey secured from the honey-dew secreted by scale insects is very dark in color, rank in flavor, and even possesses an odor that makes it quite unfit for table use. As many will remember, barrels of this kind of honey were secured in Michigan for more than one season during the very dry years of the 80's. I myself produced one year more than a barrel of such honey. I took samples to a confectioner, who made a very fine quality of honey-cookies, and he took it at a fair price, finding that it was as good for this purpose as any other honey.

If Mr. Cowan should tell me that he had personally seen honey-dew that he knew was secreted by plants, I should certainly feel convinced that I was wrong. But if he takes his evidence second-hand, I should hesitate before accepting it—I should at least wish to know that his informants were as accurate and scientific as I know him to be.

HERMAPHRODITE BEES.

I have just received one of those interesting bees, of which I have received several in years past. This bee has the head of a drone and the thorax and abdomen of a worker-bee. The eyes meet above, while the posterior legs show well-markt honey-baskets. The sting shows plainly at the tip of the body. Such cases are not very rare, and while the bees appear to be hermaphrodites, they are not really so. Dissection proves that the abdomen really determines the sex of the bee. In this case the bee is really a worker, but has a drone head. The antennae and jaws are more like those of the drone than of the ordinary worker.

CYCLOPEAN BEES.

I have another bee that is still more remarkable than are even the so-called hermaphrodites just referred to above. This bee has only one eye, which is a huge crescent, the

center of which is at the apex of the head, with its convexity uppermost, otherwise this bee is not at all peculiar. The hive from which this bee came produced several of the same kind. While this peculiarity is much more rare than the one referred to above, I have found several cases on record. It is probably a variation produced by something abnormal in the environment of the bees of this hive.

Los Angeles Co., Calif., May 2.

The Anger of Bees—Their Bravery.

BY C. P. DADANT.

THAT courage is not measured by size, is plainly proven by the bee. We have no cause to be astonished that lions, tigers, bears, or other large animals have the courage to defend their life or to attack others; the idea of valor calls before our mind's eyes the ponderous knights in steel armor, and the feats of Hercules and Samson; but that a small insect that is hardly half an inch long, and weighs but a few grains, should not only fight other insects larger than itself, but should even attack any being by whom it or its home may be threatened, whether the aggressor be bear, lion or man, and that it should usually win in the fight, is indeed wonderful. Without taking into account the number of its enemies, without considering its own feeble strength, it defends to the last its home and its stores, even at the sacrifice of its own life, since the loss of its sting is usually the cause of its death.

It is true the bees are united; Virgil says, "Mens omnibus una est" the spirit of all is one; all would rather die than not conquer, when the fight is once begun. Among these Amazons there is no such thing as moderation or restraint when the battle is on, and their ardor degenerates into fury. Not only must they win or die, but they persist in following their aggressor far from the battle-field. King David finds no better way to describe the obstinacy of his enemies than to say, "They compass me about like bees."

Brave men who have faced dangers of all sorts, as soldiers in battle, as firemen in dangerous conflagrations, have no courage before a colony of angry bees; and Della Rocca, in his treatise on bees (1790), gives two instances where bees were employed to defeat an army.

When a bee's suspicion is aroused, and she takes wing to ascertain whether the enemy is about her home, her flight assumes a special sound. Her buzzing is sharp, quick, and very different from the noise made by a peaceable worker returning from the field. This sound serves as a call, a special warning to the sisters at home. It certainly attracts the others, and informs them as plainly as a speech, that some danger is feared. You may move away ever so cautiously, if a single bee has followed you, there are ten chances to one that her angry buzzing will attract others from the same hive, unless you can manage to put a safe distance between you and the place of strife.

Slight jars, quick motions in front of the hives, and all unusual actions about the apiary are liable to anger bees. I have known the bees of a dozen hives to rush out ready to fight, from the passage of a heavy traction steam-engine close to the apiary, which jarred the ground in its passage. Yet the bees in close proximity to railroad tracks become used to the passage of trains.

They are more intractable at times during atmospheric disturbances, and their ill-nature is often a sign of an approaching storm. They have great dislike of clothes made from the covering of animals, while clothing made of vegetable fiber is less objectionable to them. For the same reason a brush made of asparagus tops, or of hemp, jute, or a whisk-broom, is better to brush them off the combs than either a hair brush or a feather broom, which they will sting with persistency. There is nothing extraordinary about this. They are accustomed to seek their living among plants, and to be in constant contact with all forms of vegetable life among the grasses, in the calyx of flowers, and about the leaves of the trees, while, on the other hand, all animal life is by them naturally regarded as a danger.

They naturally and instinctively hate the woolly fur of the bear, and all that has a resemblance to it. Thus, woolen clothes are obviously dangerous to wear, and the more woolly they are the worse is the effect. They dislike black, either because black is not a natural color among field-plants, or because it also resembles animals. They will sting a felt hat unmercifully. But Debeauvoys, in his book, says that a white felt hat is as readily attacked as a black one. They seem to know the weak spots in their enemies,

for they aim at the eyes, the ears, the nose, and the mouth, besides burying themselves in the hair with frenzy.

Nothing angers them more than fighting them, and for that reason persons who are much afraid of bees are in greater danger of being stung than those who have no fear, for they gesticulate and strike at them the moment they hear their buzz, and a bee that might pass harmlessly is apt to mistrust that something is wrong in the intentions of the person who so unwisely attracts her attention.

Hancock Co., Ill.

Some Interesting Notes and Comments.

BY EDWIN BEVINS.

SPELLING REFORM.—Now and then somebody kicks about the American Bee Journal's spelling reform. What's the use? If any of us are too old to learn new tricks, the editor says we don't have to. Just look here! Almost every one sees, or is liable to see, packages labeled, "Buckeye Rolled Oats." What a waste of time and ink is here. O my countrymen! Why is not this label printed, "Buki Rold Ots"?

BEE-SUPPLY COMBINATION.—There is a little matter of interest to honey-producers that needs a little airing. It is charged, or at least broadly insinuated, by very respectable authority, that northern supply manufacturers have combined to keep up the prices of supplies. I know nothing of the truth or falsity of this charge, but it does look as if there may be something wrong when the price of so inexpensive a thing to make as B. Taylor's comb-leveler is held at one dollar.

HOFFMAN FRAMES.—I am with Mr. Davenport in my liking for Hoffman frames for all hives not deeper than the standard. True, they get stuck up with propolis sometimes, but even then I can handle them in less time than I can handle the loose, hanging frames. As Mr. Davenport has given a means of overcoming the inequalities of spacing the Hoffman frames at the bottom, I shall like them better than ever. I have never had much trouble on account of these inequalities, but have sometimes thought that the manufacturers might have done a little better job. I never liked any spacer for the bottoms of the frames that reaches across the hives and comes in contact with the bottom-boards. Nor do I like nails or staples driven into the edges of the end-bars. Some sort of spacer, however, is necessary in hives deeper than the standard, and I have tried hard to think of one less objectionable than any I have yet tried. I will throw out a few suggestions, and ask the Roots, or some other manufacturer, to work them out to a practical result. It seems to me that a metal spacer might be made to reach across, and be permanently attached, to the ends of the hives just above their inside bottom edges, with projections pointing inward and reaching far enough to embrace the end-bars of the frames. Of course, end-bars would have to be of uniform width, and perhaps a little narrower than many in common use.

I have a sneaking fear that the kind of spacer I have here suggested will be regarded as impracticable, but I will continue to hope that something may come of it. It seems as if an attachment with curved upper edges to guide the frames into the spaces intended for them, and so slight as not to admit of the accumulation of much propolis, may have to be a feature of the spacer.

END-SPACED FRAMES. I took occasion once to write something in derogation of frames that have to be spaced at the ends. I wish now to modify what I said then, and to say that I have no disposition to hurt their inventor. You see, it was this way: That season I thought I would use the thick-top hanging frames, and somebody sent me a lot with the shortened top-bars. Of course, I had to use staples or send the frames back, and I resolved to try them. When these frames were put in a hive they would not stay anywhere in particular if the hive was jarred the least bit, but rattled around in a most exasperating way. The Hoffmanized bob-tailed frame is a very good frame to use.

TAKING AN INVENTORY—WINTERING. It is now April, and bees are flying a little for the first time in many days. The atmosphere is chilly, the frost is not yet out of the ground, the late snows are melting, and the country is one vast sea of mud. In view of the disagreeable weather conditions at this stage of spring, it may be a good thing for

bee-keepers to size up the conditions affecting their interests in the immediate future.

But, first, let us glance at the conditions that have prevailed in the recent past. Winter weather came early in November, and has had but few interruptions up to the present time (April 11). The days when bees could have a flight have been few, and the spells of confinement have been long ones. I am speaking, of course, about bees wintered out-of-doors. Great losses are reported from almost every place, and it is quite likely that the colonies that have survived are weaker in numbers, and their stores nearer the point of exhaustion than is usually the case at this time of the year. Those persons who do not examine their colonies early in the spring will, no doubt, meet with many surprises if they examine them now. Like myself, they will, I presume, find some colonies dead with plenty of honey in what would seem to be easy reach; some colonies will be found consuming the last little patch of honey in the hive, and in some colonies will be found some little patches of brood with honey so remote that you will wonder how the bees live and yet keep the brood alive.

In view of the weakened condition of many colonies, and the deficiency of stores, it seems that more than usual care will have to be exercised in order to get a large force of workers in time for the harvest. For myself, I am studying the methods lately given by Mr. Doolittle and C. P. Dadant, in the American Bee Journal and other bee-papers, believing that if anybody can tell how it is done they can.

And now as to the way my own bees have wintered. One in nine of my colonies is about the extent of my loss. I have less bees than I had last fall, but, as a partial compensation, I know more. I had hardly a loss that was not avoidable, and yet these losses were all in hives of the 8-frame dovetailed size. My colonies in hives taking frames 11 1/4 and 11 inches deep have all come thru in safety, as have those in 10-frame dovetailed hives, and those in two sections of a sectional brood-chamber hive, each section of which is 7 1/2 inches deep. But I am not blaming the size of hive much for my losses.

A part of the colonies lost were too weak to winter without uniting or having the space in the brood-chamber contracted, and I did neither. Two colonies were smothered by dead bees at the entrance, and the others, with one exception, had consumed all of their stores. The bees in that one hive had eaten their way to the top-bars right up thru the centers of the combs, and starved, it seems, because it was too cold for them to move the cluster two inches either way. A cake of candy laid on the frames in time would have saved the colony, and several others might have been saved in the same way.

The conclusion of the whole matter seems to be that, while it is not impossible, or even difficult, to winter bees in the 8-frame dovetailed hives with complete success, yet they will winter with less work and less worry in the 10-frame hive, and hives that take a deeper frame. All this may have been settled to the satisfaction of many bee-keepers long ago, but I remember that there was a good deal of controversy over the matter in my early bee-keeping days, hence my experiments. Whether the advantages of 8-frame hives when the bees are storing honey, will compensate for their disadvantages in wintering, is a matter that each one must decide for himself. Would it not be well for those who think they must use hives of standard depth to make a compromise by using the 10-frame hives when the flow comes? I borrowed this idea from Doolittle.

I wish to modify what I have said about wintering, to the extent of saying that I lost one colony wintered in two stories of the 8-frame dovetailed hives. I wintered other colonies in two-story hives with perfect success. The honey in the one mentioned was all in the upper story, and there was an abundance of it, as much as four full frames of it, well distributed, was found after the bees had died. The colony was excessively strong thru the working season, and I can account for it only by supposing that the queen had exhausted her reproductive powers so early as to prevent the rearing of young bees for the winter. When I made my first examinations in March, the colony had dwindled to a small cluster too small to maintain the necessary heat thru the cold weather that followed.

Decatur Co., Iowa.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

CONVENTION PROCEEDINGS

Report of Wisconsin Bee-Keepers' Convention.

(Continued from page 291.)

Cellar-Wintering of Bees.

In a cave or cellar prepared for the purpose in which I have quite successfully wintered for several years, the temperature is controlled by the use of air-tubes thru which fresh air can be admitted without disturbing the bees. My cellars are constructed mostly under the surface of the ground, with not less than three feet of earth over, and on all sides, except the doorways, which have three tight-fitting doors. The fresh-air tubes are 10 inches square on the inside; they go in under the doorways, and have one or two elbows to prevent the light getting to the bees.

I have another and a smaller air-tube for each cellar, which is six inches square, and goes down thru the center of the roof. From this tube the thermometer is suspended by a string. Each air-tube is supplied with a slide cut-off to wholly or partly cut off the circulation of air. I keep the temperature as close to 45 degrees as possible. A high temperature will, I think, prevent dampness.

Bees should be prepared for winter in September, and put into the cellar the first cold weather in November, usually from the 5th to 20th.

I place my bees in the cellar on a long frame made of 2x6, and one foot above the cellar-bottom. Each hive is raised above the bottom-board by sticks one inch thick placed under each end of the hive. I usually place the hives in tiers one above another five high. I leave all covers sealed down to prevent rats and mice cutting combs. I distribute rat-poison around in the cellar. I do not usually go into the cellar more than once during the winter. If the bees are put into such cellars in good condition the winter loss should not exceed 2 or 3 percent.

They should be removed from the cellar during soft maple bloom. I think it advisable to take them out in the evening after dark, and place them on stands regardless of where they stood the previous season. Their movements the next morning will be very gradual for the first hour or two, marking location, etc. No loss of queens will be caused by bees mixing. A. G. WILSON.

Vernon County.

Benefits of Attending Bee-Conventions.

Preparatory to the opening of my paper I wish to say that the smiling faces and the friendly greetings of members of this convention are worthy of note. How is it with you, my brother bee-keeper? Does it not inspire you with fresh courage? Is there not something in the pleasant visage of each that not only says "Welcome," but "we have a feast of the knowledge gained in the past 12 months for you and for all?"

Again, have we not been housed up and perplexed with other cares and duties, and allowed ourselves to become stale in the bee-industry? Can you think of any place where you can become more thoroly aroused, filled with more enthusiasm, than at the annual convention? How otherwise can we expect to get the different modes practiced by our best bee-keepers? So rapid is the progress that we cannot afford to live in the backwoods in this nineteenth century. At our conventions we are encouraged with papers and discussions to add to the knowledge imparted by the research and inventive skill and methods of our most prominent bee-keepers. Each succeeding year brings before us scientific apiculture comparatively of to-day's creation. Practice has been shown the best fitted to obtain the best results.

Then, I consider it a duty that we impart all knowledge gained from year to year, to our friendly bee-keepers. We learn at our annual meetings that bee-culture is being recognized as an important factor in the commerce of the country, and if properly fostered and encouraged it will soon grow to large proportions. Every industry in the country is represented annually or semi-annually dairy-ing, agriculture, floriculture, horticulture, manufacturing,

etc. If such conventions be beneficial, it is a fact that to succeed in apiculture we must convene regularly.

I will speak of a chapter by G. M. Doolittle in his book on "Scientific Queen-Rearing." He did not wish credit for that which was valuable in his book; he stated that he had picked up a little here and there, and the credit belonged to some one besides Doolittle. Some of the suggestions received came thru the bee-periodicals, but quite largely from the reports given and thoughts dropt at many bee-conventions.

The events of each year truly mark an epoch in the progress of our association; it has emerged from its crystal state to enjoy its higher and better fully-fledged legal existence. Thru the generous assistance given by the members of this association we have succeeded in presenting a Bill to the legislative body of our State, and by that body was recognized. The Bill was in regard to the extermination of foul brood. We now have as a recompense for our labors Mr. N. E. France as our inspector for the eradication of the worst enemy we have from our midst, and whose labors we greatly appreciate. It is not only a privilege but a duty to call attention to any evil of this kind.

I wish it were possible to induce more bee-keepers to become members of our association, with the hope of establishing a fixt price for our product, the quality governing the price. Our home markets are many times ruined by those who have only a small quantity, and perhaps inferior quality at a nominal figure.

So much knowledge is being graspt from our coming together each year and imparting to each other practical ideas and uses, that it would be like reaching out into a sea of knowledge to mention all points given worthy of note. I can only hastily mention a few. The different ways of successful wintering; the methods of strengthening weak colonies; preparation for the collection of supplies; necessary ventilation; the condition of the temperature as governing the amount of moisture held by the atmosphere; the kind of hives most practical; the most successful way of handling bees; the best honey markets; the best way to market honey and make it the most inviting; a uniform style of comb and package.

As I have already remarkt, there are many points which would be impossible for me to mention. When we try to help others we always help ourselves. We are getting at facts which would evidently help not only the producer, but dealer and consumer; as we undertake to educate others we become educated ourselves.

Since attending our annual meetings I have acquainted myself with many useful articles which lessen labor and prove a great help in apiculture. Thru the knowledge gained I have purchast articles which tho inexpensive yet they have proved valuable to me. I find I can get my wax made into foundation by those that make it a specialty, so reasonable that it does not pay me to bother with it, my machine being one of the first ones out. I have been able to purchase a machine for putting sections together and fastening the foundation at the same time, for which I am also grateful. These useful articles are labor-saving, and curtail expenses, as you do not require the hired help.

We also come in contact with "bee-ology" in all its various branches. The elements of success, however, at times baffle the best of us, and yet seem apparently easy of solution when as a body we exchange thoughts and give our various experiments. Practical apiculture rests upon more than the mere knowledge of what can be, and should be, done. It rests upon the unwritten part of our trade. How to obtain this knowledge is a matter for your careful consideration. Undoubtedly, if you were so situated as to attend every convention in your reach, and receive the advice and precepts of our most skillful apiarists, I know of no more reliable information. I can with pride say to you that the works of our own countrymen are pre-eminently the most practical and scientific. I have found them able to explain the anatomy and physiology of the bee, and its bearing upon practical agriculture. With all your knowledge, never allow yourself to be absent from our annual meetings, neither neglect the little things that impress you at the time as new, and you will soon become able to lay the foundation for success broad and strong, and when the superstructure is built it will long endure.

Green County.

JACOB HUFFMAN.

The Hive I Prefer, and Why I Prefer It.

In the first place it might be well to say that I run for extracted honey, and my crop is gathered from raspberry, white clover, bergamot, buckwheat, etc., thus making a light, continuous flow for a long period.

The hives are 13-frame Langstroth in size, and I run them three stories high, from the time it is warm enough in the spring until the harvest is about or quite over. The advantages are these:

- 1st. Less feeding and less swarming.
- 2nd. I get more honey from the best colonies.
- 3rd. They winter better than colonies in 10-frame hives in the same cellar.

To sum up, it means more honey and less labor with a large hive than with a small one. Of course I speak for my own locality.

E. M. HAYES.

Columbia County.

Apiarian Exhibits at Fairs—Their Advantages.

The first question to settle is, Shall I exhibit at the State fair or other fairs? If you decide to make an exhibit you should begin early, that is, as soon as the honey season is on.

In the first place, you must determine just what you intend to place on exhibition. If you decide on bees, honey and beeswax, the first to be attended to are the different races of bees, and be sure to see that yours are the standard in every way. The Italian bee as a standard has but three bands of yellow, no more and no less. The golden are bred only for beauty, and some points in working and swarming, but mostly for the former.

The next thing to prepare is the honey. You must have perfectly-filled cases of the different grades of honey, namely white clover, basswood, buckwheat, golden-rod, other fall flowers, etc. The sections should be of different sizes, as 4 $\frac{1}{4}$ x 4 x 2, 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$ x 1 $\frac{7}{8}$, and also include no-bee-space sections, so as to show the public in general the different styles of packages. Only the one-tier cases should be used. All sections must be free from propolis, and no leaky sections allowed.

With regard to the extracted honey, you should have samples of the different grades, as above mentioned for comb honey. This must be put up neatly in fancy glass jars, and most marketable packages, from the barrel down to the Muth one-pound jars, and be sure to show the styles of cans and tin pails used. Take both honey that is granulated and that which has not yet started to granulate, so as to show those that are ignorant of the granulation of honey how it comes about, and be always on hand to explain, for you will profit by so doing.

The night before you start for the fair have your one-frame observatory nucleus hives all ready to receive the bees you intend to take. Do not overcrowd them, for a few are just as good, and will stand the journey much better. I sometimes lose my best bees in making an exhibit, so you must not think it is all gain if you are lucky enough to get a few premiums.

The bees can be shipt, but I prefer to carry my bees with me in the coach, and then I know that they are safe. Last fall they tried to prevent my taking them into the coach with me, but I took them in spite of protest. Of course your other goods must go by freight a few days ahead of you. And here I wish to say that the only right way to ship a lot of honey is by freight, as it is by far the safest and cheapest way, and you do not need to protect the glass unless you wish. By nailing two cases together you will have a nice package that is easy to handle.

Upon arriving at the fair grounds prepare to arrange your exhibit with as much taste as possible, for your sales will depend largely upon the way this is done.

Now as to the advantages of honey exhibits. My aim has been, not only to take as many premiums as I could, but to sell as much honey as possible in small packages with nice labels attacht, showing my guarantee and full address. In this way you will be surprised when you return the next year to see your customers and their friends about you to see if that "honey-man is there again." In this way your sales will increase, and if your honey is No. 1 in every respect, you can sell it by the hundred weight right on the grounds, and take orders for more.

I have never had any trouble in disposing of my beeswax for 30 and 35 cents a pound. I have sold to certain people regularly for years, and do not intend to let any one excel me in beeswax.

I have often given away extracted honey as samples, and find that it pays. I now sell large quantities of extracted honey to private families in Milwaukee, when four years ago I could hardly get them to take a pound. One gentleman bought 150 pounds of basswood comb honey of me in 1897 for his own use, and he said that he had just used the last of it in August, 1898, and that it was as good as when he bought it.

E. D. OCHSNER.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Using Combs of Granulated Honey.

Do you mean, when you say put the brood-frame with granulated honey that one finds in the winter-killed colonies under strong colonies, that you take the hive of the strong colony off its bottom-board, put the hive with the granulated honey on it, and then set the one with the bees right on the frames without cover or bottom-board between them? I had 150 colonies die last summer with lots of honey in their hives; I think it must have been honey-dew. This is the first year I ever lost more than two or three colonies.

CARY.

ANSWER.—Yes, you have it exactly straight. The idea is to have the combs where the bees will readily get at them to take care of them. You may have no entrance directly to the upper story, forcing the bees to go thru the lower story to get to the upper one, or you may allow an entrance between the two stories. In some cases I have given a colony two, and even three, hives full of combs to take care of. If no honey is coming in you must be on the lookout for robbers when combs are first given, if there is honey in them.

Perhaps Two Queens in One Hive.

The first really warm day we had this spring, about the first of April, and the first day that the bees were out plentifully, a neighbor came to me and said a swarm of bees was on his fence about 200 yards away. As I started to go to see them I met them coming to my yard. They clustered at the root of a gooseberry bush. I examined them and found a queen, but for some reason she evidently could not fly. As the swarm was so small, and no bloom yet out, I put the queen on top the frames of the hive from which I thought she came, but soon I found her on the grass in a bunch of bees. I decapitated her. All my colonies at this time had laying queens in them and some brood. The queen must have been in the hive all winter with a fertile queen.

ILLINOIS.

ANSWER.—If I understand you correctly, each colony had a laying queen without counting the queen found in the grass. It is barely possible that the swarm came from some other place, and that the queen could fly before you found her. It is more likely that a mother and daughter had wintered in the same colony. I had a case once in which two queens not related wintered in the same colony. It would be nothing so very strange for two queens to winter together, but it seems unusual for one of them to swarm out.

Wire-End Frame—Saving Queens When Uniting Building Up Weak Colonies.

1. How is the B. Taylor wire-end frame constructed?
2. Is there any way to save the queens of weak colonies when united in the spring?
3. In building up weak colonies in the spring, do you wait until the best colonies are real strong before drawing on them, or do you equalize all colonies and try to keep them so till the flow comes?
4. Are your frames 1 1/8 inches all around? MICH.

ANSWERS.—1. It would be somewhat difficult to describe so that you would understand without seeing, and my remembrance of it is hardly clear enough to describe it even if you would understand it.

One way is to put them in cages and place them on top of brood-frames of a colony. There is some danger, however, that the queen of the colony may be killed; at any rate I once put several of them over a colony and the free queen was killed. At other times the queen has not been hurt.

3. I would never draw from the strongest colonies to

help the weakest ones. If I do anything in the way of equalizing, it will be to help those that need only a little help. For example, if I have a number of colonies that contain brood in seven or eight frames, and from that down to one or two frames, I'll take frames of brood with adhering bees from the strongest, enough to reduce them to five frames of brood, and I'll not give these to the weakest, but give a frame to each colony that has four frames of brood. If there are frames enough to afford it, I may give two frames of brood and bees to a colony that already has three frames. When these are all supplied, the two-framers may get three frames of brood each. The idea is to reduce the strong ones no lower than five frames of brood each, and to bring up to five brood any colony that is helped. If two or three frames of brood and bees are given to a weak one, it is better to have them from different colonies—safer for the queen. Of course, one must look out not to take the queen when taking brood and bees.

4. Yes, I'm not entirely sure that's best, but it's the best I know with my present light.

Quinby Frame for Queen-Rearing—Hybrids vs. Italians.

1. Do you think it advisable to use the Quinby frame in queen-rearing? If not, why?
2. Which frame would you advise a beginner to adopt—the Quinby or the Langstroth?
3. Are hybrid bees as good as Italians? MASS.

ANSWERS.—1. Yes, use the same frames you are using in general, whatever they may be.

2. That's a hard question to answer, and what might be best for one might not be best for another. In late numbers of this Journal Mr. Dadant and others have shown up the advantages and disadvantages of the different kinds. The kind that has been in most general use and has been most successful in your own neighborhood, other things being equal, is the one to adopt. The smaller frames have the advantage of being in more general use, and are easier to move. If your hives are to stand in the same spot from one year to another, and you are working for extracted honey, you might consider the Quinby.

3. The hybrids are as good for work as the Italians, providing they are good hybrids, for they will work just as industriously, and a cross, making a change of blood, tends to vigor. In some respects the hybrids are inferior. They are crosser, and their progeny will be likely to work backward. While the first cross may do as much work as the pure Italians, the progeny of the Italians will stand many chances of being crosses, and I'd choose the pure stock every time.

A Queenless Colony.

I have a colony that is queenless, and being unable to get a queen so early in the season, on April 14 I put in two frames of sealed brood and eggs, the lower part of one of which containing drone-comb but no eggs. I cut away, to keep up the strength till I could get a queen. On the 16th I looked in and found two queen-cells begun where I cut away the drone-comb, but could see nothing in them. To-day (23rd) I looked again and found both cells sealed over—one had a queen in the imago form, the eyes just turning pink. But what I wish to ask you is this: There were about a dozen sealed cells amongst the worker-comb which projected far beyond the others, like drone-cells, the pupae of which were as large as that of a drone. I unfortunately destroyed them, thinking they were queen-cells, since which I have begun to wonder if they could be drones changed by the workers from worker-eggs, which I see from my book some authorities say is possible. If not, what were they? I am in hopes I have overlooked one or more; if so I will see what they turn out.

B. C.

ANSWER.—Very likely they were queen-cells, which are often found projecting very little above the general surface. It is also nothing very unusual to find an occasional case of drone-brood in worker-cells, for some cause the eggs not being fertilized. There is no necessity to resort to the supposition that the workers changed an egg that would produce a worker into one that would produce a drone; and if you care for my opinion in the matter I am free to say that I don't believe such a thing ever happened. I wish you had said in what book you found such a thing mentioned; I've seen it in papers, but I think never in a book.

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39. MAY 18, 1899. NO. 20.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Changes in Apiarian Fixtures Deprecated.—N. D. West, in the Canadian Bee Journal, objects to fences and plain sections. He objects to changes in general, because they cost, and by the time all make them we are no better off than we were before; but he rather lets the cat out of the bag in giving reasons against fences by saying that 25 years ago he tried them. So he has done the very thing he objects to in others. But he has good sense on his side when he says that the man who makes some costly change to get ahead of others is only making expense for the whole fraternity, and in the end no one is any better off. Your head is pretty level, Mr. West.

The New York Honey Market.—Mr. J. E. Crane, of Addison Co., Vt., spent some time in looking over the honey market of New York city last December, and tells about it in an article in Gleanings, from which we take these paragraphs:

Remembering the experience of the late Moses Quinby in shipping honey to that market, when, in 1860, 20,000 pounds broke down the market completely, and much of the honey was carried over the following year before it was sold, I inquired how much honey was now taken by the same market, and was informed that there was no trouble in disposing of about 6,000,000 pounds yearly, about five-sixths of which was extracted honey; that while, formerly, there was a demand for honey but a part of the year only, now there is a demand the whole year round. These facts

were of much interest to me, as the prospective demand for honey is one of great interest to every honey-producer.

I might say incidentally right here that, previous to 1875, or about that time, there was, so far as I know, no New England city where honey was regularly sold at wholesale. A little was sent to Boston or other cities and sold to any one who would buy, or left to be sold on commission by any one who was willing to handle it, or, perhaps I should say, who could be trusted to do so; but I have the impression that most retail dealers, previous to 1875, in New England, went to New York for their honey. To-day several New England cities have wholesale dealers, some of them doing an immense business. These facts show the immense increase in the demand for honey during the last 30 or 40 years.

Two or three years ago we investigated the receipts of honey in Chicago, and came to the conclusion that there must be, in a good honey-year, about twice as much honey handled in Chicago as in New York, or something like 1,200,000 pounds. This would give about six pounds to each person living in Chicago, while it is now estimated that the per capita consumption of sugar in this country is 64 pounds. We all need to urge the more general use of honey.

Honey a Cure for Smallpox.—Mr. Chas. Dadant has kindly sent us the following item which he clipped from a newspaper:

MEXICO CITY, MEX., Dec. 26.—Experiments made with smallpox patients in Oaxaca, show that by administering honey diluted in water to smallpox patients the pustules of the worst variety disappear, and the fever is immediately diminished. The matter attracts much attention. The remedy was accidentally discovered by a young girl who was down with the disease, who secretly refreshed herself with honey and water, with astonishing curative results, and it was then tried on soldiers sick with the disease.

Mr. Dadant wrote us the following note when sending the foregoing paragraph:

FRIEND YORK:—Please advise all the bee-papers to publish it, for if honey proves to be a good medicine for smallpox, it will be a great succor to mankind, while its use will help the bee-keepers to dispose of their crops.

CHAS. DADANT.

We might say that in the Bee Journal for Jan. 21, 1897, we published the same item, word for word, excepting it was then dated "Dec. 28." Mr. F. Bussler, one of our Mexican subscribers, seeing the item in the Bee Journal, wrote us the following letter, which we published March 4, 1897:

MR. GEORGE W. YORK, Chicago, Ill.

Dear Sir:—I saw your statement about the honey-cure for smallpox, and I can tell you that it is really true. Here in Mexico that disease comes nearly every year, when the rainy season finishes. This year it has been pretty bad in some places. The authorities are trying hard to get rid of this malady, but the Indians are very little educated. In nearly all the papers the honey-cure was published, and for this reason I sold my honey as soon as I got it out.

Yours respectfully, F. BUSSLER.

The Relative Cost of Comb and Extracted Honey, along with the question as to which is more profitable to produce, seems to be one of the problems never to be fully settled, and it is perhaps well that it is so, for if all found it best to produce only extracted honey, the possibility is that the price might be reduced, and a market for comb honey left unsupplied. In Gleanings the editor argues in favor of getting the bees to start promptly in the sections by first giving them a super of shallow extracting-combs, then putting under a super of sections. Dr. Miller thinks a single bait-section might do about as well, and objects to having part of the honey put in extracting-combs that might make white section honey. Then the editor urges that with prices in proportion of 6 cents for extracted to 10 for comb, counting all expenses on both sides there may be more money in the extracted.

Awful Adulteration of Foods.—At the last session of Congress, at Washington, a committee was appointed and an appropriation made for the purpose of conducting an investigation of the foods consumed by the people. Senator Mason, from Illinois, we believe was the author of this initiatory effort, and for the past week or two his pure-food inquiry here in Chicago has been treated to a revelation along the line of adulteration that is simply awful to contemplate—and of course worse than awful when it comes to swallowing the poisons that the adulterators have put into some of the foods we eat.

Here is a list of astonishing facts that just one day's probing brought to light:

That a commodity for sale thruout the United States, and in popular use among dairymen and milkmen for the preservation of milk and cream, and by bakers for the preservation of cream puffs, chocolate eclaires and similar pastry, is a product of wood alcohol, which is absolutely poisonous; that this preparation is used by undertakers for the preservation of dead bodies, and by health authorities for the disinfection of buildings where virulent diseases have been treated.

That ground tarred rope has been used to adulterate ginger.

That absolutely pure flour is a rare commodity; that it is adulterated with ground stone and clay from Tennessee and Georgia.

That pure buckwheat flour is rarely to be purchast after it passes thru the hands of a jobber or a wholesaler; that one barrel of pure buckwheat flour is generally mixt with two barrels of inferior spring-wheat flour that can be purchast for less than one-third the price of the buckwheat.

That nearly all powdered sugar is composed in great part of cornstarch.

That nearly all black pepper is adulterated with what is known as "buckwheat shorts" (hulls).

That retail butter dealers in this city daily violate the oleomargarine law.

That flavors sold at sodawater fountains as the juice of strawberries, bananas and pineapples are chemical compositions.

That pure vanilla extract for flavoring purposes is almost unknown, and that the flavorings for such extracts as are sold in the market are in the main derived from cumarin; that lemon and other flavoring extracts are also adulterated to a very great extent.

Dr. H. W. Wiley, the Government chemist, has been here to give testimony before the committee, whose work is simply preliminary, as we understand it. We believe that when it completes its investigations there will have been compiled such a mass of evidence regarding adulteration of foods that Congress will be compelled to enact a strong anti-adulteration law in order to put a stop to killing people with poisonous mixtures, not to say anything of the fraudulent side of the subject, which is simply appalling. Why, it seems there are plenty of people who are perfectly willing to sell poisons as food if thereby they can only put a few more dollars into their pockets. Highway robbery isn't "in it" when compared with some adulterators of foods.

Mr. G. M. DOOLITTLE, in the May American Bee-Keeper, gives these words about new things in bee-keeping:

"There is much of value and merit in nearly all the new things put forth, when properly developd, but I cannot think that the using of these things as the 'cat's-paws to pull the chestnuts out of the fire,' as some do, before they have settled down and become an establish fact, and the booming of them in the reading columns of a purchast pub-

lic publication is very greatly in advance of what used to be termed 'highway robbery.' Catalogs, circulars, price-lists and advertising columns are the places for booming, if such must be done, and not in the columns which are purchast by subscribers for their instruction and advancement."

But it was a rather strange coincidence that in the very same issue in which was the above paragraph, also appeared, in the reading columns, about two pages devoted to booming what is called "a new hive," giving illustrations, etc. Mr. Doolittle should labor with Editor Hill before he "goes for" some other people.

MR. R. B. LEAHY and his company, of Missouri, have recently been given a write-up in their local newspaper, which had this to say in regard to them:

"In 1883 R. B. Leahy, then a struggling day laborer, made his appearance in this city, and for a time found employment doing odd jobs for several of our oldest citizens. Soon after his arrival here he opened a little wood-shop and began his life's work, that of building bee-hives and kindred supplies. His largest and most expensive piece of machinery at that time was a foot-power saw. With this he

workt early and late, and by severe perseverance he added to his plant, little by little, until he was so fixt that his work and output attracted some little attention.

"In 1890 he started the erection of his present plant, and, being short of finances, succeeded in interesting John J. Jas. E., F. M., and E. B. Gladish sufficiently to form a stock company, of which he retained a half interest. This stock company was organized under the name of The Leahy Manufacturing Company, with a paid-up capital of \$8,000, R. B. Leahy was appointed general manager and treasurer, and Ed. B. Gladish, general

R. B. Leahy.

foreman of the shops. The business has been continuously under the same management since, and the present business is a sufficient proof that it has prospered.

"Late last fall it became necessary to again enlarge the plant, and a new brick addition was built, which, with the new and improved machinery added at that time, doubled the capacity of the plant. They now occupy a two-story brick building, 54x130 feet, thoroly equipt up-stairs and down with the best improved machinery. In addition to the main building they have several warehouses, their wax-room and tin-shops being under separate cover.

"In the busiest season, which is now on, the plant is run day and night, and from 35 to 40 men and boys are employed during this period. That this factory is a great boom to labor has been duly demonstrated, over \$10,000 being paid out here last year for labor alone. Sixty-five carloads of material was consumed in the manufacture of goods sold last year, which amounted to over \$30,000."

"TWO SWEETHEARTS OF MINE" is the name of a song received by us from the publishers a few days ago, the melody and words of which are very pretty. The song complete, words and music, will be sent to any address for 20 cents in silver or stamps, by the Groene Music Publishing Co., 32 East Fifth St., Cincinnati, Ohio. Send for it, mentioning that you saw the notice of it in the American Bee Journal.

To Prevent Cakes of Wax from Cracking, William McEvoy winds papers around boards and covers the pans so tightly that no air can get in, and has not had a cake crack for 20 years. The secret probably is that this prevents rapid cooling of the surface.—Bee-Keepers' Review.

Divisible Shallow-Framed Hives have not proved a success with G. M. Doolittle. In the Progressive Bee-Keeper he reports that he gave a *faithful* trial of the Heddon divisible system with from 15 to 20 colonies in such hives for four or five years, and averaged less than two-thirds as much as from the other colonies in the same apiary.

Times when Bees Don't Rear Best Queens sometimes occur, according to the veteran queen-breeder, Henry Alley, in Gleanings. Just after the honey harvest in July he thinks is the worst time to rear queens. The bees seem to want a rest then. From the last of July to about the first of September he thinks a good time to rear the very best queens.

The Value of Pollen, according to M. Bellot, in Revue Internationale, is much greater than it is generally supposed to be. Three colonies began brood-rearing in December, and he gave them every 10 or 12 days pollen that had been stored in other hives. Three combs were kept filled with brood, the population was doubled by March 20, and he estimates that each colony used three to four pounds of pollen.

Boiling Foul-Broody Honey seems to be a troublesome matter to settle fully. Prof. Hodge, in Gleanings, advised separate boilings, on different days, so that the spores

might have a chance to vegetate between times and then the bacilli be killed. Now comes Harry S. Howe, in the same paper, and says this will not apply to foul-broody honey, for spores will not develop in honey, and bacilli will live in honey only in the spore stage. So the boiling must be long enough to kill the spores. Mr. Howe inclines to the view that 15 minutes is sufficient to boil foul-broody honey, the boiling-point of honey being from 225 to 235 degrees, according to the density of the honey. On the other hand, H. W. Brice says in British Bee Journal, "No boiling alone will destroy the spores while they remain in that condition." Evidently there is room for more experimentation to clear up the whole subject.

Rendering Wax.—In melting old combs, A. C. Miller advises, in the Bee-Keepers' Review, that the combs be placed in a strong solution of sulphuric acid in cold water about a week before melting, and if the combs are well broken up and occasionally stirred, the acid will decompose the pollen and cocoons so that a large part will remain when the crushed combs are removed for melting. Melt slowly and don't allow the wax to *boil*, else the propolis will combine with the wax. Always add acid enough to neutralize any alkali in the water that might form a kind of soap with the wax.

Prevention of Swarming seems to be more and more considered desirable, and less and less considered attainable. Nowadays there is not so much said about the great advantage that comes from the extra vigor of a newly-lived swarm, and all efforts possible are made to have as little swarming as possible, and when swarming does occur, there are probably not a great many who allow the division of forces to be just as the bees would naturally adjust the matter, but the bee-keeper tries to keep a strong force in the new colony with comparatively little regard to the strength of the old. H. H. Hyde probably voices the opinion of a large number, when he says, in the Progressive Bee-Keeper, that "by far the greatest hindrance to successful comb-honey production is swarming." Despairing of entire prevention, he limits swarming by abundance of timely super-room, a free communication separator, and blocking up hives so as to give plenty of air at the bottom.

MAY.

Behold, she comes, the spring's beloved,
The pride of earth and sea,
With blossoms on her pulsing breast
From glen and glade and lea,
So light of step, so fair of face,
She passes on her way;
With every beauty, every grace,
The rare and radiant May.
— Farm Journal.

Bees Are Busy.

The past winter was the most severe, as low as 28° below zero. I lost 3 out of 28 colonies. All kinds of fruit are in blossom, and the bees are very busy. I could not keep bees without the American Bee Journal. Long may it live and prosper.

I. D. HYDE.

Washington Co., Mich., May 7.

Many Lost Thru Severe Cold.

Bees are booming, but many have lost large numbers of colonies on account of the severe cold weather. The losses, however, are with those who ought not to complain, as proper attention was not given the colonies in the fall. It is ever thus.

Success to the American Bee Journal.
F. A. GEMMILL.

Ontario, Canada, May 3.

Wintered Without Loss.

My 36 colonies wintered without any loss. I winter them in the cellar with bottom-boards on. My neighbors lost almost all of theirs, still they would not spend a dollar for a bee-paper! Success to the "Old Reliable."

G. JOHNSON.

Clark Co., Wis., May 1.

Feeding Bees—Honey Prospects.

Will you allow me to correct Cogitator, as to my plan of feeding bees, as given on page 225? Instead of feeding every tenth hive, as stated, I reserve the surplus of every tenth hive, in full-sized frames, to feed the nine, in case they need it.

I claim it is poor policy to feed liquid honey to a starving colony, as it only stimulates brood-rearing, to require more feed. I am speaking more particularly of carrying bees over a dry year in California. If comb honey is fed bees they will economize and save feed. In carrying bees thru a dry year all we need is a normal colony. We do not need a surplus of bees when there is nothing to gather.

I am having some prospects of part of a crop of honey. I have had 40 new swarms from 64 colonies, and some of the swarms have filled their hives. But generally prospects are poor in California.

CYRUS C. ALDRICH.

Riverside Co., Calif., April 30.

No Winter Loss—Honey-Dew.

The past winter was the coldest ever witnessed in this part of the country. I began the winter with 36 colonies packed in forest leaves, on the summer stands; they all came thru the hard winter all right, and didn't get out to the soft maple which is in great abundance here, till April 17, and now they are all just booming. I never had my bees in such a nice, healthy condition, and in such good shape at this time of year.

While I suffered no loss in wintering, some of my neighbors report heavy losses, some losing three out of five colonies. I don't know what gave me such success, unless the American Bee Journal did it. I credit my "good luck," as my neighbors call it, to that source.

The summer of 1898 was noted for honey-dew. There was more of that here than

SWEET CLOVER

And Several Other Clover Seeds.

ever witness in these hills, and with the exception of a little in the beginning which was very dark, it was rather yellow and sweet, and most of the people seemed to like the taste of it, except the first gathered which was as black as old-fashioned cane molasses.

I hear so much pro and con about honey-dew that I wish to tell what I saw last summer. About June 23 I was going across the country and watching the honey-dew; it seemed to be in every place and on all kinds of leaves, even the weeds were covered with it. It being about 8 a.m., I lookt across under the sun, and I could plainly see the honey-dew falling, and it was coming from above the tree-tops. Now, where was it coming from unless the insects that produced it were flying in the air above the tree-tops? This is the conclusion that I have reached.

Let some of the big lights tell, who think that honey-dew is produced by the leaves on certain timber. I for one feel sure that a great percent of honey-dew is the production of the flying insect family.

Success to the American Bee Journal and its many readers.
IRA SHOCKEY,
Randolph Co., W. Va., April 20.

Bees Came Thru All Right.

My bees came thru the winter all right, but as a rule bees came out of winter a little weak. Fruit-bloom is on now, and they seem to work with unusual vigor. My first virgin queens hatch to-day. H. G. QUINN,
Huron Co., Ohio, May 6.

Bees Wintered Well.

My bees wintered well on the summer stands, packed in leaves. I am going to try the fence and plain sections this year.
IRA LUBBERS,
Sheboygan Co., Wis., May 8.

Unpacked Colonies Died in Winter.

Our bees have wintered well here, and are now in tip-top shape, and working every day on fruit-bloom. Nearly all the farmers have lost all their bees—in fact, I don't know of a colony that was not packed that lived thru. EUGENE HANBAUGH,
Brown Co., Ill., May 3.

Very Backward Spring.

This has been a very backward spring. Bees had done very poorly until the last few days.
J. A. ROSSON,
Ellis Co., Tex., May 4.

Good Prospects for Honey Crop.

The past winter was the most disastrous on bees that we have had in this locality since I have kept bees. The average losses will run over 50 percent, my own being 25 percent. Bees generally are weakened, and their only salvation lay in the propitious weather that has prevailed during the past four weeks. There have been only one or two days during that time that they could not forage and gather if there was anything for them to get. The bees are holding high carnival on the sugar maples at this date, which are blooming profusely this season (something that has only occurred twice in 7 years), and are building up very rapidly considering the weakened condition that early spring found them in. The prospects are very good, I think, for a honey crop for those who have any bees left.
D. W. HEISE,
Ontario, Canada, May 8.

Indian Territory Fine for Bees.

The past winter was severe on my bees, and I lost a few colonies. I winter them on the summer stands. I have the advantage of a fine climate and large range of native bee-pasture. My bees commenced to swarm April 27, and up to date I have 7 swarms, and in all 90 colonies. I have my new hives

put up and painted nicely, and am now wiring and placing in foundation. In this work I am assisted by two nice Cherokee Indian girls. (Now, say, you young fellows that don't believe this part of my letter, just take a trip down to this splendid country and see it and me, and—yes, the girls, too.)

I have a neighbor bee-man 40 miles away, a pleasant correspondent, Mr. Hairston, of the Saline district, Cherokee Nation. There is room for more bee-men here. We are expecting a change of status soon, after which outside or non-citizen people can come and settle in this fine country. We will want not boomers but good, industrious home people. After I add that this is a fine climate, that all grains, vegetables and bees, too, do well, don't ask questions, but come and see.

W. M. A. SCOTT,
Cherokee Nation, Ind. Terr., May 5.

May Weather in April.

The weather has been very warm here, and we had May weather in April. Cherry-blossoms are first here, and they have just opened.

GEORGE CURTIN,
Middlesex Co., Mass., May 1.

Prospects Not So Favorable.

Prospects for a good season here are not as favorable as I wish they were; and I lost heavily in bees last winter and early spring. I have only about 100 colonies left, that are in condition to amount to much this season.

C. MONETTE,
Fillmore Co., Minn., May 5.

A Hard Winter on Bees.

The past was a bad winter on bees. I believe fully two-thirds of the colonies died in this part of the country. I lost 35 out of 47 colonies. Nearly every one that had bees lost all. It didn't make any difference how good care had been taken of the bees, as those in the cellar and in the house died all the same. I put one colony in the coldest place I knew of, where the northwest wind had the best sweep; I didn't care for them, and wanted to freeze them out, but they came thru all right, and are very strong. Three-fourths of those I had in a nice, dry cellar and house, and took extra care of, are dead, and so it is with everybody else's bees.

CHAS. SCHMUCKLE,
Bureau Co., Ill., April 14.

Heavy Loss of Bees.

There has been a big loss of bees in this neighborhood. Nearly all are dead that were wintered out-doors. A good, warm cellar was the best the past winter, where they were left in till near April. March was a hard month on bees; they died with plenty of honey in the hives. About 75 percent of all the bees are dead in this neighborhood.

NOAH MILLER,
Iowa Co., Iowa, May 5.

A Hunting Trip and Report.

I have been trying to get time to write you ever since I returned from my annual hunting and trapping trip. I came home two weeks ago. I had a fine time, altho it was very cold; Feb. 13 it was 7 degrees below zero. I did not do as well this winter as I have done some other winters, but I caught 219 coons, 61 minks, 2 otters, 57 opossums. I caught 2 wild hogs alive, one weighing 147 pounds, the other about 100. Deer are scarce. I saw only one all winter, and no bears.

When I got home I look over my 210 colonies of bees, and found a few had frozen, perhaps 10 or 15. I bought an apiary about six miles north of here last week; they are all good Italians and hybrids. The owner died last August. I got 83 strong colonies in 10-frame hives, all double-story, painted, 57 empty hives, one sun extractor, 1,000 Hoffman frames, and a honey-tank holding 137 gallons, one new Cowan extractor, 1,000

EVERY BEE-KEEPER WILL APPRECIATE THIS.

MARSHFIELD, WISCONSIN.

sections, about 10 pounds of foundation, and 27 pounds of beeswax, and lots of other tools, all for \$85. I have worked this apiary since 1892, and have never taken less than 600 gallons of honey in any season, and some years with less bees than there are now. I shall divide up my home apiary, try to increase by natural swarming, and try and keep about 400 colonies hereafter.

Score one more for the golden Italians; they winter and build up better than any bees I ever had.

I can't very well get along without the American Bee Journal. **J. H. SIPLE.**
Bolivar Co., Miss., March 15.

"Up to Her Eyes" in Honey.

I am "up to my eyes" in honey. I began extracting last Friday, and got six gallons from the first hive. I have a dozen supers of sections ready to take off—all "neat as wax," "white as snow," and filled with "nectar fit for the gods." My bees wintered on the summer stands without any protection whatever. My first swarm came off March 25. Our honey-flow seems only begun. The American Bee Journal is a great helper.

MRS. M. M. DUNNEGAN.
San Patricio Co., Tex., May 2.

Lost All Wintered Out-Doors.

We had 13 colonies of Italian bees last fall, all in good shape. We wintered them out-doors packed in large boxes with straw, as we always had done before, but they all died, leaving lots of honey. Our neighbors' bees that were wintered out-doors are also dead. Bees that were stored in cellars did well. We are sorry that we lost our bees, but we are not going to give it up. We have bought two colonies again.

We like the Bee Journal so well. We find such good reading in it. Long may it live.

MARY J. BEIGHTS.
Buena Vista Co., Iowa, April 20.

A Great Utah Honey-County.

Here in Uinta County we are 125 miles from the nearest railway shipping point at Price, on the line of the Rio Grande Western Railway, or 100 miles south of Green River City, Wyoming. On the north are great mountain ranges that stand as a barrier between Utah County and civilization. On the east and south for many miles stretch the bad lands of western Colorado and eastern Utah; on the west lies the Uinta Indian Reservation, over which travel must go to reach the railway at Price.

"What has that got to do with bees?" you ask. Well, only this: That in spite of all these obstacles, Uinta County is fast gaining a reputation as one of the best honey-producing sections of the State, if not of the West. The honey produced here ranks very high in the market, both for flavor and color, and bee-keepers are very enthusiastic in consequence. The bees find unlimited pasturage of alfalfa, greasewood, and white clover, besides many wild flowers at certain seasons. The greasewood is very early, and the bees will be working industriously on it now in a few days. The flow of honey under normal conditions is above the average.

The business has been conducted in a rather haphazard way in the past, and honey of the very finest quality has been put upon the market, in cans of all sizes, and in barrels, or anything that could be obtained. Despite these drawbacks, and the lack of united effort on the part of the bee-men, the good quality of the article has been recognized, and the business now bids fair to become one of the leading, if not the leading, industries in the county.

The Uinta County Bee-Keepers' Association was organized the past winter, and matters are now assuming definite shape. Pres. C. C. Bartlett is very enthusiastic over the outlook, and, in a report read at a business men's meeting recently, gave out the statement that if the business increase

at a normal rate for the next two years. Uinta County would produce 1,000,000 pounds of high-grade honey per annum.

The output for last season—which was a poor year—was 300,000 pounds. The bee-keepers are having cans manufactured here for this season's crop, and have placed an order for 4,000 60-pound cans as a starter, with more contracts to follow.

There was a very heavy loss in bees a year ago, but the winter just past has been mild, and the losses have been very light. The faces of the bee-men are wreathed in smiles, as a great season is anticipated. Shipments are made as far as Chicago on the east, and Butte, Montana, on the north. A 10-ton shipment of old honey was sent out last week, consigned to eastern points.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, May 8.—Not anything of consequence doing; a little honey is being sold at prices that have been prevailing for some time. White comb is scarce, but there is a surplus of dark. Extracted unchanged. Stocks light. Beeswax, 27c. R. A. BURNETT & CO.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10 1/2c; dark and amber, 8 1/2c. Extracted in fair demand without change in price. Beeswax, 25 1/2c.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey. M. H. HUNT.

NEW YORK, May 9.—Fancy, 7 1/2c; choice, 6 1/2c; fair, 5 1/2c; common, 5 1/2c per gallon. Beeswax quiet at from 26 1/2c to 28c, according to quality.

Our market is in first-class condition, being bare of extracted honey, and demand good. New crop is beginning to arrive from the South. Comb honey is well cleaned up; some demand for white but demand for dark has ceased.

HILDRETH & SEGEKEN.

SAN FRANCISCO, April 26.—White comb, 10 1/2c; amber, 7 1/2c; extracted, white, 7 1/2c; light amber, 6 1/2c. Beeswax, 26 1/2c.

Light supplies of both comb and extracted operate against any special movement in honey. Prices remain quietly as before. New crop honey will be on market in about 30 days, but the yield is certain to prove light, and there will be very little white sage, which is the best grown.

BOSTON, April 13.—Fancy white, 13c; No. 1, 11 1/2c; A No. 1, 10 1/2c; light amber, 9c. Extracted, stocks about cleaned up. Nominal price for white, 8c; for light amber, 7c. Beeswax, very light stocks; selling at 27 1/2c.

Naturally the demand for honey is gradually growing less, and altho stocks on hand are not large, still the demand is so small that the general feeling is weak and prices are being shaded in order to work off stocks.

BLAKE, SCOTT & LEE.

KANSAS CITY, May 11.—No change in the honey market. Trade at this time of the year is naturally light. There is nothing on the market except some very dark New York buckwheat comb honey which meets with rather slow sale at 10 1/2c. A correspondent in Texas advises us that he will be ready to ship new comb and extracted honey shortly.

PEYCKE BROS.

CLEVELAND, March 9.—Fancy white, 13 1/2c; No. 1 white, 12 1/2c; A No. 1 amber, 10 1/2c; No. 2 amber, 9 1/2c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.

A. B. WILLIAMS & CO.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11 1/2c; some very poor selling at 6 1/2c, and dull. No more business in honey before the opening of the ensuing season.

BATTERSON & CO.

OMAHA, April 18.—There is but little stock left in dealers' hands now, and realizing that no further receipts can be expected until another crop gets into the market, it is held firm at 14c for fancy white comb. Extracted, 7 1/2c.

PEYCKE BROS.

Nuclei of Bees For Sale.

We have arranged with a bee-keeper in Lee Co., Ill., about 100 miles west of Chicago, Ill., to fill orders for 3-frame (Langstroth) Nuclei of Italian Bees, with Queens, in light shipping-boxes, at \$2.75 each, or in lots of 5 Nuclei, with Queens, at \$2.50 each. Address,

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

Brood-Frame for Comb and Extracted Honey.

BY C. A. BUNCH.

HAVING used the Simplicity-Langstroth frame for 13 seasons, I think it is all right for the production of comb honey, and I like the frame first-rate; but for the production of extracted honey I would like the frame about two inches deeper. I find the frame is too shallow, as Mr. C. P. Dadant well says.

My hive for extracting has 12 Langstroth frames in the brood-chamber, and the supers are the same length and width, and hold 10 frames 6 inches deep, which make an ideal super, only that the queen is very apt to go up from the shallow Langstroth frames below and lay eggs in the extracting-combs, which causes the bees to store all, or nearly all, the honey there about the eggs and brood, which does not suit me, as I want my bees to feed themselves for winter, and place the honey in the brood-nest, enough at least to winter on.

I consider this a serious fault, but very little is said about it, and I think I will never change to a deeper frame for the brood-chamber, as it would cost too much, but what I have said may be the cause of the beginner in apiculture investigating the matter, which might be to his advantage.

FULL SHEETS OR STARTERS IN SECTIONS—WHICH?

Full sheets of foundation in sections, or starters $\frac{3}{4}$ inch deep— which shall we use? For myself I want to say it is a well known fact that full sheets of foundation in sections do not of themselves secure a crop of honey. Bear this in mind.

After experimenting along this line for years, I have time and again filled sections one-half to three-fourths full of foundation and placed them carefully on the hives only to take them off a couple of months later to scrape them and put foundation in them again. And why? Just because we had a poor season, and the bees borrowed said foundation and carried it down below. But a good season would cause drone-comb to be built in the sections, that Editor Root says would be more "gobby" eating, which I think is more imagination than real harm. Am I not about right?

REPORT FOR THE SEASON OF 1898.

I commenced the season with 87 colonies of bees in fair condition, increased to 92, and took off 1,200 pounds of honey, about two-thirds extracted and one-third comb, which is far below the average of my apiary—27 pounds.

Marshall Co., Ind.

Height to Which Sweet Clover Grows.

BY W. W. LATHROP.

THIS picture was taken to show how high sweet clover grows in my back yard. I am 5 feet 9 $\frac{1}{4}$ inches tall, and I hold a two-foot rule in my hand, which shows that the clover at that end of the row is 9 feet high.

The plants in the foreground are cleome pungens and gladiolus; at the right, blackberries and tomato vines; in the background, a plum and an apple tree; and in the shade of these are my five hives with bees, one of which can be seen.

Fairfield Co., Conn.

Hauling Bees to and from Out-Apiaries.

BY C. DAVENPORT.

FOR the benefit of those who haul bees to and from out-yards, I will describe the screens I use and the manner of fastening them to the hives. No nails are used, yet they are more firmly and quickly fastened over the top of a

hive than can be done by the use of nails. While there are hive-hooks made and designed to be used for such purposes, they have not proved (with me) very satisfactory, and when nails are used the hives in time become damaged, for in order to be sure the nails will hold it is necessary to drive them in a new place each time, and I much dislike to mar or damage hives in any way, for they are an important part of the means by which I earn a living, and also enable me to lay up a little each year for old age, or a rainy day, as the saying is.

Altho my method of fastening screens to hives without the use of nails or marring the hive in any way is so simple and easily employed that probably many others have made use of it, I do not remember ever seeing anything said about it. There are, without doubt, many who have not thought about it, and some time ago one of the great honey-producers of California, who hauls as many as 150 colonies at one load, described the kind of screen he used; and altho he had tried hooks he preferred nails instead, but seemed far from being satisfied with nails as a means of attaching screens over the top of hives.

The screen I use is large enough to cover the entire top of the hive, and I will say here that I consider it a very important matter when hauling bees to give them plenty of air, as the jarring and disturbance cause them to fill themselves with honey, and arouse them to such activity that they generate much more heat than when in a normal condition. While in some cases colonies can be moved without much provision being made for the ventilation of the hives, and not actually smother, I do not think they do so well for some time afterwards.

The frames for the screens should be made so that the wirecloth will be up at least an inch above the top of the brood-frames. Some of mine are made of inch thick pieces about two inches wide, and halved together at the corners. The wire screen is tacked over the entire top, and then pieces of lath are nailed on top of it around the edges, so the edges of the wire will not be turning up and catching things, or cutting one's hands.

Tho I have the frames of these screens made in various ways, they are all of such size that when placed on top of a hive the outer edge of the frame is just even or flush with the outside of the hive on both sides and at each end. In other words, the frame is just the size of the top of the hive.

After a frame is made so far, I take eight pieces of lath for each frame, that are about three inches long, and nail two pieces on each side, and two on each end of the frame. They are nailed on near the corners on the outside of the strips forming the frame. The top or upper end of each of these short pieces of lath are just up even with the wirecloth, so the lower part of them hangs or projects down on the outside of the hive.

Now, if I have made myself understood, it will be seen that the screen, on account of these short pieces, cannot be shoved or moved out of place, either sidewise or endwise. The only way it can get out of place, or be removed, is by being raised up. To prevent its raising up, two stout strings (or perhaps very small rope more nearly expresses what I use, something like a small cotton clothes-line), are tied around the hive, bottom-board, screen and all. They are placed one near each end. If, however, the frame fits down true on the top of the hive, and there is no danger of the load being upset, one string near the center is ample. If the frame does not fit true it can easily be brought down tight, when a string is used at each end. A screen can be tied on in less time than nailed, and if tied tight enough it will hold the screen surer than nails will.

I will briefly cite an incident in support of it: One spring I sold four colonies, and was to deliver them to the buyer, a few miles away. There was one place on the road where there was a high embankment off to one side, and when I arrived at about the worst place, the horse I was driving—a powerful black one that I had recently traded for—suddenly whirled almost square around, and upset the wagon so that I with the hives went down the embankment. Screens were tied on as I have described, and none were loosened or out of place except on one hive, which struck on a rock and was badly broken up.

There is quite a knack about tying strings around a hive, but it is easily acquired. I have a loop on one end of each string, and pass the end without the loop under the hive, then up thru the loop; the string is then placed so that the edge of the loop is even with the outside of the frame. I then draw it tight and hold it from slipping or loosening with the left hand, while tying the knot with the right hand. These strings cost but a trifle in the first place, and will last so long that they are about as cheap as nails.

I use loose bottom-boards, and have special ones for hauling, which are made just the same as an ordinary bottom-board except they have short pieces of lath nailed on at the sides and on the back end, which project up and prevent the hive-body from moving sidewise or backwards. To prevent its moving forwards, and to close the entrance, blocks are used that I will describe, for depending upon a simple strip to close the entrance, with bottom-boards that have strips around the outside to form the entrance, like the dovetailed bottom-board, with me has sometimes caused trouble. I take a strip that will just fit between the strips on the bottom-board so it will entirely close the entrance, and which is about 1¼ inches wide. Then I take another strip which is long enough to reach clear across the bottom-board, but which is only ¾ inch wide. Now to make myself clear I will say, take the shorter strip and shove it in at the entrance until only about half its width is left out in front, then take the longer and narrow piece and lay it over or on top of the short piece that projects out in front, and tack the two together with small nails that can be clincht. To hold it in place when moving, two wire nails are driven in the bottom-board in front of it. With this kind of block, if the body of the hive moves nearly an inch on the bottom-board either backward or forward, no bees can escape.

A bee-keeper who saw my screens made some in a little different way. The frames of his were just the size of the top of the hive, but the strips forming them were only 7⁄8 inch wide, and instead of using short pieces of lath nailed on the outside to hold them in place, he used short pieces of thick iron that had two holes in one end, and one piece was fastened at each corner of the frame on the inside of the 7⁄8-inch strip, so that these irons fitted down inside the hive. While he considered this way an improvement, I prefer to have short pieces of lath on the outside, as they prevent the hive's themselves from coming close enough together to rub or chafe the paint off. Southern Minnesota.

An Experience with Bees in Wisconsin.

BY HERBERT CLUTE.

IN the spring of 1895 I moved here from Mauston, Wis., where the large honey crop the year before showed Clark County to be as good for honey in quantity as well as quality as any place in this State, of which the latter is the very best as to color and flavor. That spring (1895) I traded my bees at Mauston toward a one-third share in one car-load of bees that Mr. Grimm, of Jefferson, Wis., had, and which were purchast by Frank McNay, and placed in my care here.

We had a very bad freeze here on or about May 25, that killed all basswood blossoms, so as to make things look very discouraging, as the bees hardly had a pound of honey thru July to breed on, except what little the raspberries furnisht.

On Aug. 1 they began to swarm, and the hive on scales commenced to gain, the first day's gain being 3½ pounds. All thru August there was a lot of rainy weather each week that would check the honey-flow so that sometimes it would be a couple of days before the bees would gain as before. The honey harvest lasted until Sept. 5; on that day the colony on scales gained 5½ pounds, there being that day a hot wind so as to take all life out of the flowers, it checkt the honey harvest so as to stop all the nectar from flowing as before, and from then on the bees never gained an ounce of honey, still there was fine weather and lots of flowers. From the car of bees, or 100 colonies, there was an average of 100 pounds besides an increase of 28 colonies, and 400 new combs drawn out for extracting.

The next spring, 1896, the apiary was all moved 1¼ miles west, to the other side of town, just inside of the city limits, as the year before the bees all workt in that direction, on the river bottoms, which made 1¼ miles that was useless for them to travel.

That spring (1896) there was another car of bees purchast in chaff hives from Hartford, and turned in as before with 50 other colonies that I had purchast at Neilsville. All the bees were divided in two apiaries, one apiary for home yard and the other for an out-yard, which was located five miles southwest from the home yard. That season they gave a surplus of 30,000 pounds of honey, gathered from July 1 to the 30th, from basswood and willow-herb. That fall the out-apiary was brought in and placed with the home yard, and kept together from that time on, for the reason that both apiaries took more time to do the same amount of work than if both were together; and for another reason, the bees in each yard workt the heaviest

toward each other, as the big slashing lay between the two yards showed that if they all had been together there would be just as much honey gathered, besides less work to tend them all.

The season of 1897 was a very poor one in Clark County, as well as over the most of the State. In the springtime here it was very cool and rainy; strong colonies of bees dwindled down to nothing, which found lots of empty hives at the commencement of the honey-flow, which began about July 4, and lasted until July 25. The apiary gave but 25 barrels of basswood honey.

The season of 1898 was another poor one, which made two poor seasons in succession for the bees, as there was only an eight days' honey-flow that came in July from basswood. It gave an average of only 75 pounds to the colony, of extracted honey (as there is no comb honey produced in the apiary), besides plenty of honey for wintering.

The bees in chaff hives seem to do the best in the apiary, except in early spring they don't seem to get the benefit of the sun as do the bees in single-walled hives, so as to breed up as early. The rest of the season they are far ahead of single-walled hives, especially for honey.

Each chaff hive has 10 frames below (Langstroth size), and 14 to 16 above, the same size as below; while the single-wall hive has only 8 frames of the Grimm-Langstroth size.

The best day's gain in the season of 1898, in an 8-frame Langstroth hive, was 12½ pounds, while on the same day the best gain in a chaff hive was 21½ pounds. The hot days and cool nights didn't seem to affect the bees in the chaff hives as much as in the single-wall, as the wall prevents the heat from entering, which seems to save the bees lots of labor in ventilating the hive; still, the entrance of chaff hives is not as large as the others for air.

Last winter was my first in trying to winter bees in the cellar. Eighty colonies in chaff hives were placed in the cellar, and 20 left out on the summer stands. Out of the 80 in the cellar there were 80 strong colonies taken out in the spring, while of the 20 out-of-doors 10 died, or 50 percent.

There would be an improvement on the chaff hives for winter if the top part was in band or oven shape, so as to be taken off, and not to occupy so much room.

My honey extractor is a Van Allen & Williams 4-frame reversible. It is very handy on account of the comb-basket being so near the top. The extractor is kept fastened on a stationary bench made out of match ceiling, 8 feet to the left from the corner of the house, up just high enough for a pail to work handy under the faucet. From that on, running toward the corner of the building, there is another bench 8 inches higher running past a large window fitting snug to the extractor, with a square hole cut in it for uncapping the combs on, and to hand to the one that is turning the extractor.

For a capping-box there is a washtub set under the hole in the bench. From the corner running to the right there is another bench built 9 inches lower, in sink shape, running past another window for light to come in to give plenty of light on combs as they are being uncapped. This bench is for a washdish and pail of water, so as to keep the hands from being stuck up, by dipping the ends of the fingers in the water once in awhile. At the end of this sink-bench there is another bench built barrel high, 8 feet from the corner running to the right. This is for an extra-large barrel to rest on to strain the honey in; also to help ripen the honey, and the common 30-gallon barrels are stood up under a faucet and filled here.

By having the honey-extractor at the left 8 feet, and the strainer barrel at the right 8 feet, it gives a chance for the one that is extracting to carry the honey across the corner, and not be in the way of the one that is uncapping, but saves room, and keeps all the dauby muck from the drippings of honey from the extractor, uncapping-box and strainer-barrel, all in one corner of the house.

With the sink-hole being placed under the strainer-barrel bench, by throwing a pail of water up by the extractor, and with the use of a broom a couple of times or so through the day, the floor will keep clean, and the dauby muck won't have to be trod in. By keeping the floor cleaned, and the water being run in a drain, the bees never bother the bee-house by trying to get in.

Over each window is a row of bee-escapes that keeps the house rid of bees that are brought in on combs, and flies also.

The bee-house is two-story, 18x30 feet. The upper story is to store barrels, to work in, etc.; while all the honey is stored on the lower floor. The bee-cellar is made of white oak, 6x8 two feet apart, and plankt.

The bee-yard is graded into a sidehill, the upper side

being a 4-foot cut, while the lower side is filled in 2 to 3 feet, which leaves the bees high and dry, and still near spring water. Trees are all around the grading, which keeps the wind from the bees. By the bee-yard being graded it gives a level entrance to the bee-cellar, which is built in the bank, to take the bees in and out.

Our honey-plants and honey-producing shrubbery here are, first in the spring maple-juice from the large maple trees (as quite a lot of maple syrup is made here), besides the sap from the stumps where the trees were cut for saw-logs, as there are carloads of the logs shipt from here every year. This sets the bees to breeding very early in the spring, as they sometimes gather 5 to 6 pounds to the hive.

Next comes tag and black elder that furnish lots of pollen, with willow of several kinds out about the same time, which furnish pollen and honey. Poplar and birch-elm of several kinds blossom, and the bees breed up fast; and as the wild cherry, plum and thorn-apple blossom the bees begin to swarm, the first swarms beginning to come off about the first of May. Each of the latter three trees are so thick as to make the woods look white when they are in blossom.

Dandelions are very thick here, and help the bees out in feed the most of any of the honey-plants until basswood bloom. White clover is thicker here than in almost any other part of the State, but the bees hardly ever notice it except in the latter part of its bloom, then once in awhile there is a day that they work out it well.

Raspberry blossoms come next to the dandelions, and the bees get a little honey from them so as to keep up breeding in good shape until the basswood sets in. At the same time the basswood blooms the willow-herb blossoms. The bees get the nicest honey from the willow-herb and asters; of the latter there are several kinds, but they don't yield honey every year.

Buckwheat is very seldom noticed by the bees here for some reason, the same as white clover.

The farmers are just beginning to raise Alsike clover here, and it grows very rank; the bees work on it very well. As the land gets cleared up more, so the ground will be warmer, and farmers get to raising more clover, the honey harvests will begin to get still larger each year. The first year that I was here there was not an acre of Alsike that I knew of. The past summer there was a little sown by most of the farmers.

Grocerymen claim their customers like our honey flavor better than any other. One of the grocerymen lets the honey candy in the barrel, then he sets the barrel of honey on a table in the front part of the store, and cuts all of the hoops from the barrel, then pulls the staves off. In that way it leaves one big lump of candied honey on the table right in the show-window; the customers come in and inquire what that big chunk of sugar is. He tells them that it is honey, and then they wish to buy a few pounds, and he takes a large knife that he has lying beside it, and slices off on the top edge as you would cheese. In this way he sold a barrel of honey a week, at a profit of 4 cents a pound, while the two adjoining groceries sold but a barrel or two all winter, of the same kind of honey, as it was shipt from me at the same time. But the others kept it in the barrel. They had the barrel up at the front of the store, but there was not enough curiosity excited in that way to create an appetite, as was the case with the large cake.

Clark Co., Wis.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 50 cents; 50 for 70 cents; 100 for \$1.25; 250 for \$2.75; 500 for \$4.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year - both for only \$2.00.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

GETTING THE PUBLIC TO EAT HONEY.

The Chicago convention was just level on the subject of getting the public to eat more honey. First reach their ears; and then be careful about putting any ill-tasting honey into their mouths. Don't you know, honesty, altho the *right* policy, is not always the *best* policy? Best policy sometimes has to go a long way beyond honesty. It's honest to sell poor honey, if you make the customer understand just what he is getting; but it's better policy for you not to do anything of the kind—kill your customers, and you haven't got any too many now.

HIVES WARM IN SPRING AND FALL AND COOL IN SUMMER.

But how to have black (the warmest color) on the hives spring and fall, and white, the coolest color in the summer, that problem seems rather to have floored the Chicago convention. Pres. Beers' suggestion of painting twice a year was none too practical. Tough job to paint a black hive white. A black hive completely shaded in hot weather seems to have been the nearest they got—none too near. Page 229. No one said double-walled hive, with the outer shell painted on both sides, and so joined at the corners as to be capable of being turned inside out. I have made a good many unpainted hives look respectable and white by tacking on cheap cotton cloth. I rather like the plan. In similar style a black hive could be surfaced with white cotton for summer, and "peeled" for autumn, if any one thought the matter important enough to pay for the trouble.

MAKING THE HONEY-LEAFLET EFFECTIVE.

The honey-leaflet (see editorials on page 232) is not self-enforcing, as indolent temperance folks would like a prohibitory law to be. Not much use to throw them around, in this day of advertisements knee-deep. But if you can afford to stir up a person's interest a little in the first place, and then give him a leaflet, some results will be likely to follow. In short, the leaflet, like any other tool, must have a workman to use it.

CURIOUS REASON FOR PROSPERITY OF BEES.

"Johnstown," on page 231, has a curious reason for the prosperity of bees in the Heddon hive—don't get meddled with so much by their bee-feverish master. Very possibly that would cut quite a figure in some cases.

BANKING HIVES WITH SNOW "LONG-IDEA" HIVES.

Mrs. Axtell's experience (page 251) is quite an unusual one, and her prompt way of meeting it seems commendable. Bees taken out of the cellar April 1, or thereabouts, and before they had any flight a foot of snow came. Next, some enticing sunshine came along, and of course the poor bees, having been restrained all winter, wanted to fly. Now some say that bees which die on snow are merely bees that come out on purpose to die, and the only proper course is to let alone. Mrs. A. evidently belongs to the opposite (and I guess more numerous) party who regard as a calamity a grand flight when soft snow covers everything; ergo, she kept them in with well-bank snow. She doesn't narrate the end of the struggle, whether it proved like holding a dog by its ears or not. The bee's strongest flight-maxim seems to be to keep its back toward the illuminated half of the cosmos. The snow-covered ground being brighter than the sky, it tries to fly with its back toward the ground and makes a wreck of his voyage. Even if it gets up and starts again, inborn obstinacy makes it do the same thing right over again, until too cold to fly at all.

And so Mr. Poppleton still uses and champions the long-idea hive. First we know it will have another run; and if so we want to keep in mind some things told us on page 227. Neither Langstroth nor Gallup frames suitable (needs a deeper frame), and 16 frames not enough; hive should hold 24 at least, and a capacity of 28 would be better.

QUEENS LAYING AT WILL.

Paragraph 6 of "Beedom Boiled Down," page 250, hardly sounds candid, altho in a measure correct. The

queen *can* lay at will. She also can refrain from laying for a certain length of time. What she cannot do is to refrain *indefinitely* when fully distended with ripe eggs. Probably the length of time she can refrain differs greatly under varying circumstances—time much less when she is laying 1,000 eggs a day and 2,000 on Sunday, than when only depositing 200 a day. In order to have Mr. Dadant's remark amount to much of anything, we would have to infer that the queen, in the ordinary quiet of existence in an 8-frame hive wastes eggs for want of any place to lay them. Cogitator, for one, doesn't propose to believe that without considerable proof.

"FIGHTING UPON THE INTRODUCTION OF A QUEEN."

There is an inference in paragraph 9, page 250, that might as well be halted to await proof. Natural enough to infer that a queen cannot be harmed when not a hostile bee can touch her; but when the whole cage is balled solid with infuriated bees, ejecting poison, and the queen has to exist for hours in an atmosphere thick with poison, it looks as if she *might* be damaged to some extent thereby. Cogitator has a suspicion that half of that pint of dead bees were not killed by stings, but by too great and long-continued nerve excitement, aided by poison taken otherwise than by injection.

FEARS EXCESSIVE AS TO APIS DORSATA.

I rather feel that our editor and Dr. Miller are excessive in their fears of *Apis dorsata*, if allowed to run wild in the South. May be they are right, tho. Looks to 'Tater as if the decrease of regular honey crops by such a cause would be small, if not infinitesimal; while the enlargement of the poor man's resources, by gathering beeswax, and his larder by gathering wild honey, would be quite cheerful in these days of monopolies, and of destruction to the independent means of livelihood.

EX-EDITOR ABBOTT DESERVES HOMAGE.

Homage to the man who would rather be *ex-editor*, and a clean man, than fat-*ex* editor and his hands sooty with degrading and swindling advertisements. This means E. T. Abbott—see page 249. Also, I like the ring of Abbott's article on page 245. Not of *more* importance for us to bark at the big financial seizers and Caesars than it is for us to get after flat, straight-out dishonesty in the sales between man and man.

"AGIN" THE FEEDING OF SUGAR SYRUP.

On page 245, W. W. McNeal also stands up for common honesty, dealing stalwart blows to the practice of stuffing the brood-chamber, just before harvest, with sealed sugar syrup. And he gets in a left-hander that some of us had not fully considered before, where he says that such a performance (in addition to its dishonesty) "will most certainly be done at the expense of brood or numerical strength."

A DANCING ELDER AND THE RHEUMATISM-DOCTORS.

And so the Elder, who doesn't believe in dancing, danced when the little hot-tailed rheumatism-doctors got in their work. Well, they enred the patient in 24 hours, which regular doctors do not always do; and they were rather unique among successful physicians in making no charge—that is, no charge except charge bayonets. See page 244.

SLIGHTLY CLIPPING QUEENS RATHER RISKY.

Clipping queens *slightly* before mating, to insure mating near home, must be risky indeed if the Michigan Agricultural College had only 4 mated out of 62 so clipped. Page 241.

IMPURE MATING AFFECTING THE QUEEN HERSELF.

It is of interest to see, on page 244, that Doolittle casts in his lot with those who hold that impure mating affects the *queen herself*, and thru her exerts a *slight but perceptible* influence on her drone offspring. Of course this is much less than the one-half influence exerted on the female offspring, but there is no use to deny its reality (if it is real) as it is perfectly comprehensible, and not unscientific. Cogitator (in a mild way, and on other people's observation rather than his own) joined the same crowd quite awhile ago.

Experiments to settle the matter positively should be made. Mr. D. well points out, on German bees, or some really pure race, not on such a high-mixt and sport-inclined race as the Italians.

HOW ABOUT DIFFERENCE IN MATING?

And the boys will surely ask how it is that at Mr. Doolittle's out-apiary one queen out of six showed extra-banded

blood from five miles away, while at Mr. Hutchinson's (page 241) none of the queens misnamed when the undesired blood was put back three miles. "Locality" again—but there's a locality called "The Noddle," that oft has an atom or so to do in some of these matters where doctors disagree.

COGITATOR.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY HERMAN F. MOORE.

The third quarterly meeting of the Chicago Bee-Keepers' Association was held March 1, 1899. The printed program had been mailed to about 150 bee-keepers in and near Cook County, the resulting attendance being the 50 without the hundred. Total paid membership is now 50, making our association of half a year's life the largest city bee-keepers' association in America, if I am correctly informed.

The meeting was a great success, as any one might readily infer from an inspection of the printed program. Four reasonable topics were discuss. Dr. C. C. Miller was present, and helpt in his characteristic way to make the meeting interesting and profitable to all who attended.

Pres. C. Beers opened the session with an address on the aims and objects of our association, pointing out clearly and concisely the pathway to success in our chosen pursuit.

A committee composed of George W. York, Mrs. Fannie Horstmann and H. M. Arnd, was appointed by the president to draw up resolutions expressing the sense of our association on the Pure Food Law then before the Illinois legislature, and also the Foul Brood Law, and a resolution endorsing the aims and objects of the United States Bee-Keepers' Association. This committee reported a set of resolutions in the afternoon, which were adopted without change, after some discussion, as follows:

RESOLUTION ON THE PURE FOOD LAW.

WHEREAS, It is well known to the public that honey in liquid form, as well as nearly every kind and character of food, is adulterated, and yet labeled "pure;" and

WHEREAS, Many of the adulterants so used are unhealthy and injurious to the human body; and

WHEREAS, Most, if not all, of the said articles so adulterated are fraudulently sold under false labels and false representations; therefore, be it

Resolved, That the Chicago Bee-Keepers' Association does recommend and urge the passage of the Pure Food Law about to be brought before the legislature of Illinois;

Resolved, That copies of these resolutions be forwarded to Gov. Tanner and our representatives in senate and house, and that every bee-keeper in Cook County by letter or personal call urge their representatives to vote for the passage of the Pure Food Bill.

GEORGE W. YORK,
HENRY M. ARND, } *Committee.*
FANNIE HORSTMANN, }

RESOLUTIONS ON FOUL BROOD.

WHEREAS, The contagious bee-disease commonly known as foul brood is destroying the honey-bees in portions of the State, and is gradually spreading; and

WHEREAS, This, like all contagious diseases, should and must be suppress by prompt and vigorous means before the honey-bee, one of the most important factors in successful agriculture, and the great apicultural industry of this State is ruined; therefore, be it

Resolved, That the Chicago Bee-Keepers' Association recommends and urges the passage of the law for the suppression of foul brood among bees in this State, which has been introduced in the Illinois legislature by Representative Kumler, of Sangamon County; and known as House Bill No. 103.

Resolved, That copies of this resolution be forwarded to Gov. Tanner and our representatives in senate and house,

and that every bee-keeper in Cook County, by letter or personal call, urge their representatives to vote for the passage of the Foul Brood Bill.

GEORGE W. YORK,
HENRY M. ARND, } *Committee.*
FANNIE HORSTMANN, }

RESOLUTIONS ON THE UNITED STATES BEE-KEEPERS' ASSOCIATION.

WHEREAS, The bee-keepers of the United States have a common interest in the pursuit of apiculture, and the benefits and profits arising therefrom; and

WHEREAS, A society called the United States Bee-Keepers' Association has been organized, having now about 500 members, and national in character; and,

WHEREAS, The objects of the said association as set forth in its constitution are: "To promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey, and to prosecute dishonest commission men;" and,

WHEREAS, To carry into full effect these various objects of the said organization will require much money; therefore, be it

Resolved, That the Chicago Bee-Keepers' Association in convention assembled does hereby express the fullest confidence in the ability and aims of the officers and directors of the said United States Bee-Keepers' Association, they being eminent in the pursuit of bee-keeping, and well known all over our land for their integrity and enthusiasm in their chosen pursuit; and, be it

Resolved, That each and every member of our Chicago Bee-Keepers' Association, and every bee-keeper in Cook Co., Ill., be, and are hereby advised and urged to join the United States Bee-Keepers' Association, and pay the annual dues to Hon. Eugene Secor, of Forest City, Iowa, general manager and treasurer of the association named.

GEORGE W. YORK,
HENRY M. ARND, } *Committee.*
FANNIE HORSTMANN, }

The first subject—"How I Handle My Bees in Early Spring," was to have been opened by Dr. A. B. Mason, of Ohio, but his paper, which here follows, failed to arrive in time for the meeting by about 12 hours:

How I Handle My Bees in Early Spring.

To the Chicago Bee-Keepers' Association:

Your secretary has taken the unwarranted liberty of giving me an invitation to attend this meeting of your association, and whether I can be with you or not, to give you a paper on "How I Handle My Bees in Early Spring," and saying that I may aid you "in bringing out some new ideas."

To the first part of his request I should be most happy to respond by being with you, but distance sometimes does more than "lend enchantment," and in this instance prevents my enjoying the pleasure and profit I am sure would be mine if I could be with you, and I shall have to content myself with the hope that I may aid you in bringing out something that may be of use to some of you who may have had but little experience in our truly fascinating, and oft-times profitable, pursuit.

I am glad your secretary didn't ask me to give the best method of caring for bees in the early spring, because I'm sure I should be "called down" by some for not being on the right track, that is, the way *they* do, but I can tell how *I* do, and your most cranky member can't make me lose any sleep over what he may say, for I'll not hear it.

I like to begin to "handle my bees in the early spring," along about the last of the September or first of the October previous to putting them out of the cellar in March or April, and altho it has been a long time since I began my "early spring" handling in any other way, I have not forgotten how I used to fool away my time and damage the bees with my spring foolishness.

Perhaps you'll say I can't begin my early spring work in September or October, but I can, and do, and I begin in this way:

Before the first *killing* frosts come in the fall, while some honey is still being gathered, and as soon as possible after removing the surplus, I thoroly examine every colony for three purposes—to learn as to the exact condition of the colony as regards bees, brood and stores; and as I use an 8-frame Langstroth hive, with a tight bottom-board in summer and no bottom-board in winter, I proceed as follows:

I take a hive-body with a loose bottom-board, and set it

by the side, or in the place of the one to be examined. I then lift out each comb and examine it, and if all is satisfactory I place it in the empty hive, and do the same with each comb, arranging them in this way. If the hive faces the south I put a full comb of honey next to the east side of the hive, and if it faces east I place the full comb at the south side. I then place the combs containing brood next to the one filled with honey, and as near as may be in the same relation to each other as they were before I began the examination. I then fill up the balance of the hive with full combs of honey, or enough to last until an abundant supply comes in the spring.

If there is not such a supply of honey in the hive as will be an abundance for winter stores, I take full combs from supers that have been left without extracting for this purpose. I have followed this plan of preparing my bees for early spring handling for over 20 years.

Then when settled cold weather puts in an appearance, which in this locality is generally about Nov. 12, all are placed in the cellar without bottoms to the hives, where they remain until such time in the spring as they become too uneasy to safely remain longer, frequently remaining in the cellar until many of the soft maples have past out of bloom.

Before removing the bees from the cellar, if I decide to give them spring protection, I place a box made for that purpose on each stand before removing the bees. This box is made of five separate pieces—bottom, two sides and two ends—and these pieces are made of half-inch lumber of any convenient width, being held together with cleats $1\frac{1}{2}$ inches, or less in width, at each end, these cleats being placed at such distance from the ends of the side and end pieces as will allow them to be put together as shown by the sample corner sent with this, the cleats having been cut half an inch shorter than the sides and ends are high. The sides and ends are made of such length as will make the box four inches longer and wider inside than the hive is outside, and about six inches higher than the hive-body. The bottom is made of the same kind of material as the sides, and of such width and length as to go inside the box. The cleats on the bottom are placed at least two inches from each end. The box is held together at the corners by small wire nails or hooks.

When the box is ready, or at any convenient time before wanted for use, the bottom is covered with chaff or fine-cut straw to the same depth as the thickness of the cleats it is put together with, and a hive bottom-board put over the chaff, resting on the cleats and chaff. I keep the box covered from storms with a board made like the bottom, but wide and long enough to project over two or three inches on all sides. The bottom-board to my hives is long enough so that when in place in the box it projects beyond the front of the box which has to be cut to fit it, and makes an entrance to the hive.

In taking the bees from the cellar each hive is set on a bottom-board, and the entrance closed to keep the bees from escaping. The hive is then set on scales and weighed, each having been weighed when put into the cellar. It is then carried to its summer stand, and lifted from its loose bottom and set in place in the box prepared for it.

When all are in place, and the entrance fixed, I fill the space between the box and hive with chaff, or some substitute for it. It takes but a moment to do this, pressing it down just enough so that it will not settle of its own weight.

If I haven't extra bottom-boards I can get along nicely with only one extra one, by having the chaff or other material in place on the bottom of the box; the bottom-board released by lifting the hive from it to place it in the box, can readily be put in the box where wanted.

I use enameled cloth to cover the frames, on top of which is a rimmed cover, and I fill with chaff only to the top of the hive; I then cover the enameled cloth with several thicknesses of newspaper, and replace the cover.

I keep the entrance opened or closed, as the weather may indicate, so as to help the bees maintain a proper temperature in the hive, frequently closing the entrance at night and during cool days.

As soon after the bees have had a good cleansing flight, as the weather will admit, I examine every comb to learn about the strength of the colony, the amount of brood and stores, and whether queenless or not. If I find the colony in a satisfactory condition, I close the hive and let them alone for ten days or more, according to their apparent condition as seen from the outside, or by turning up a portion of the enameled cloth.

If I find any colony short of an abundance of stores and otherwise in good condition, I supply the lack by removing

one or more combs having the least honey and no brood, and supply their places with combs more or less full of honey, that have been saved for this purpose from the previous year.

If I find a colony weak in numbers, but strong enough to be worth building up, I put the bees on as many combs as they can profitably use, and contract the brood-nest with a division-board, making sure that they have plenty of stores. Sometimes I put the colony in the center of the hive, using two division-boards, and fill the spaces between the division-boards and sides of the hive with chaff.

If I find a colony queenless I make the entrance as small as will allow the bees rather a close passage to guard against robbing, and leave it until a pretty cool evening, when I remove the covering of the weakest colony with a queen, and place a queen-excluding honey-board in place of the covering, and when all are quiet carefully set the hive with the queenless colony on it, leaving off the bottom-board. The bees of the queenless colony will readily go to the colony with the queen, and, in my experience, without any quarreling. I have united weak colonies in the winter in the cellar in this way, leaving out the queen-excluder, and had no trouble.

If I find colonies with queens too weak to be profitable, I remove such queens as I care least for, and unite two or more as may seem best, as above, uniting but two at a time.

If I don't find plenty of unsealed honey in the hive I uncap some, unless the bees are able to gather some from the fields, for they seem to build up more rapidly when they have a supply of uncap honey.

In a week or ten days, more or less as circumstances may indicate, I give another examination as at first, treating them in the same way. Sometimes, but rarely, I find too much honey in the hive, being so full that the queen does not have the room needed for depositing eggs. In such cases I replace one or more combs of honey with empty, or nearly empty, ones, always leaving an abundance of stores.

If I do not give spring protection I do just the same as where protection is given, only that when I give the first examination I furnish each colony a hive with a tight bottom in this way:

I nail a bottom to a hive-body with four nails an inch and a quarter long. That will hold the bottom on firmly, and still permit of its easy removal when I prepare the bees for winter quarters. I remove the colony I wish to examine from its stand, usually placing it in the rear of where it was, and place the empty hive with the tight bottom in its place. I then proceed to remove the combs from the full hive to the empty one, examining them and arranging the entrance according to the needs of the colony, and the weather.

When the combs have all been removed from the old hive, any remaining bees are brushed or shaken into, or down in front of, the new hive.

The loose bottom is then nailed to an empty hive which is then ready for the colony next examined. This process is repeated until all have been examined, and each colony is treated in the same way as where spring protection is given, but I much prefer to have all colonies protected.

I keep a record of everything I do to a colony, and also what it does. This record I keep either on a piece of heavy card-board, a piece of section, or a small piece of smooth, thin board, like a piece of planed shingle.

Your secretary didn't ask me to give any reasons for my way of doing, but perhaps he will allow me to say that after a good deal of experience in stimulative feeding in the spring, I have found that with plenty of sealed stores in the hive the bees will do the best for me in getting strong colonies. Of course, the queen must have room to "spread herself." I have also experimented in spreading brood to hasten brood-rearing, but it takes too much time and attention to make it at all profitable for me. □

Lucas Co., Ohio. A. A. B. MASON.

(Continued next week.)

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

The Premium offered on page 254 is well worth working for. Look at it.

QUESTIONS AND ANSWERS

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

T Supers Shorter than the Hive.

In your answer to "Missouri" on page 279, you say: "No, the T supers are shorter than the hives and don't need anything to fill out the ends." I would like to know what kind of supers you use shorter than the hives. Mine are the same length as my hives and I don't need anything to fill out to the end. The case holds 24 sections, and they fit up close to the end. I would like to have some more of them, but I believe the manufacturer has gone out of the business. Do you know of any one that is making that style? I sent to Mr. — for some T supers, and he sent me some slat supers, and I don't like them a little bit. I want nothing but T supers with the T turned upside down when in use.

IOWA.

ANSWER. The T supers I use are of the plainest kind, the sides and ends being of 7/8" stuff and the inside measurement 17 3/8 x 12 1/8". Of course that must be shorter than a hive that takes frames 17 3/8" long. Some object to the looks of a hive with a shorter super on it, but it isn't best to sacrifice too much for looks. If yours are the same length as your hives, the super being for 44 sections, and the hive taking frames 17 3/8" long, then the ends of your supers must be made of stuff thicker than 3/8". I prefer to dispense with the additional weight, even if it doesn't look quite so well. I think you ought to have no trouble in getting T supers from any of the leading manufacturers. Certainly no one should send you slat supers if you order T supers. Possibly you merely ordered supers without specifying what kind, for Mr. — is agent for —, and they have T supers in their list. But they make the super the same length as the hive by adding a cleat at each end, which is not a bad plan.

Combs of Honey Left by Dead Colony.

I have eight frames of comb left by a colony that died recently: they are all partly filled with honey and some are mildewed. What can I do with them? If I put them under a colony will not the queen take possession and lay there? Or can I have a swarm on them in their moldy condition?

JERSEY.

ANSWER. Nothing would be more desirable than to have the queen take possession and lay in the combs, if she needs the room. If desired, however, an excluder could be put between the two stories. It would be better to have the bees clean up the combs before offering them to swarms, as a swarm is more fastidious about such matters than a colony having brood, and might not be willing to stay on mildewed or moldy combs.

What to do with Empty Combs.

I lost some bees the past winter, and they left some nice, bright combs. What can I do with the empty combs?

KENTUCKY.

ANSWER.—There is no better way than to let the bees of a strong colony take care of them till swarming-time. See reply to "Cary," on page 311.

Making Increase by Dividing.

Would you advise in making one increase from each parent colony as follows, to take one frame which has the queen and bees on it and put into a new hive just when the old colony has new queen-cells started? I don't wish to buy a new queen for the old colony. I have movable-frame hives.

INDIANA.

ANSWER.—Of course it will cost you less money to follow the plan you propose than to buy new queens. Whether it will work all right depends somewhat upon further details. If you mean that as soon as you find queen-cells

started you'll take one frame of brood with adhering bees and queen, put it into a new hive on a new stand, leaving the old hive without further attention, it won't do at all. But you might wait till one or more cells are about ready to be sealed (the difficulty is to know just when that is, for as soon as one is sealed the colony is likely to swarm), then put your frame with brood, bees, and queen into the new hive, brushing into it also about half the bees from the old hive, set it on the stand of the old hive, leaving the old hive beside it, and a week later take the old hive away and set it on a new stand. There would be no advantage in that over letting the bees swarm naturally, but from your question it is a possible thing that you cannot be on hand to take care of the swarms.

Young Bees Thrown Out.

1. Mornings, when I go to my bee-yard, I find young bees on the bottom-board dead. Some are white yet and some are brown. What is the trouble?

2. I find some worms on the bottom-board. Do they crawl out, or do the bees carry them out? NEW JERSEY.

ANSWERS.—1. If there are many of them, it is to be feared that the bees are about at the starving-point, and are sucking out the juices of the larvae and throwing out the skins. If, however, they are fully matured young bees—which may be the case from your saying some are brown—then the probability is that the wax-worm has made the trouble by making its silken galleries through the brood-combs.

2. Likely they were thrown out of the combs by the bees.

Black and Mouldy Combs.

I wish to ask about two colonies I bought one month ago. They were in very poor shape, and after it got warm enough to examine them I found the combs mostly all black and mouldy, and dead bees piled up on the bottom between the combs. I got them into a clean, new hive all right, and they seem to have started to work. Of course, I had to put the old frames that had honey in them into the new hives with some frames of foundation, but the combs in the old frames are all out of shape, and I wish to have them replaced with new frames with sheets of foundation. Will it be safe to take them away from the bees when the fruit-trees are in bloom? or when would be the best time to do it?

WISCONSIN.

ANSWER. If your bees are busy on fruit-bloom or any other flowers, you may make the change at once, but likely you may as well wait till they are at work on clover. Indeed, it will be easier to make the change when the colonies are stronger, and you must look out not to waste any worker-brood that may be in the old combs. One way is to have these crooked combs with brood in another story either above or below the one the queen is in, with a queen-excluder between. The combs that have no brood in them may be taken away at any time without ceremony, providing it doesn't take away honey that they need. But don't feel troubled about the blackness of the combs. That's just what the bees like.

Entrances in the Supers—Excluders.

I am desirous of knowing whether, if in running for extracted honey and using honey-boards, the bees would gather, or rather fill up the supers, more readily, if the entrances were made in them? If this would not work well, how should I go about it? Do you think I would obtain more honey by not using excluder-boards?

We are having a fine season of it this year. Bees are gathering immensely from the logwood (which we have in abundance). I shall take pleasure in sending a sample of this (logwood) honey, next mail. JAMAICA, April 25.

ANSWER. Entrances in supers from outside have been tried, but I don't remember that any one who has tried them has reported favorably. There seems to be a desire on the part of the bees to enter where the brood is. Moreover, if bees entered supers without first entering the brood-nest, they might put more pollen in supers than would be desired. It's better to have no pollen in extracting-combs.

The general opinion is that it is better to use excluders, and that they are no great hindrance. If you have your brood-chamber large enough, there is not so much need of excluders.

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., Chicago, Ill.

ONE DOLLAR A YEAR.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,
15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

MAY 25, 1899.

NO. 21.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Canadian Pure Honey Bill. The text of this bill, for which S. T. Pettit worked so hard, is given in the Bee-Keepers' Review and in Gleanings, in which appears the following proviso:

"Provided that this Act shall not be interpreted or construed to prevent the giving of sugar in any form to bees, to be consumed by them as food."

This does away entirely with the charge that the bill was intended in any way to punish a man for feeding needy bees.

"Supply-Dealing Editors" is the heading of an editorial in Gleanings in which Editor Root "talks back" a little to Messrs. Doolittle and Hutchinson, who seemed to feel a brake was needed with reference to booming new things. He says fence separators are no new thing, nor are plain sections. For about ten years plain sections have been used by Mr. Aspinwall, and fences by Miles Morton. B. Taylor, W. S. Ponder and others advocated the same general scheme years ago. He mentions that thick top-bars had been used by J. B. Hall and others for years before Dr. Miller and he began to push them, and he gets in a sly dig at Doolittle, by saying that Doolittle at first opposed these same thick top-bars and now advocates and uses them. He does not claim that drawn foundation was an entire success, but as the experiments and necessary machinery

cost \$2,000, and less than 200 pounds of the product were sold, thus making the loss fall upon the manufacturers, he thinks bee-keepers ought not to complain very bitterly, especially as the new thin-base foundation has resulted. Even if some of the things advocated have been abandoned, Mr. Root says:

"In order to make progress in any branch of industry, some things have to be tried and discarded. In the apicultural world it would be strange if something did not have to be thrown overboard."

The Official Year-Book. The Department of Agriculture's Year-Book is ready for distribution. An edition of 500,000 copies has been provided, of which 470,000 will be at the disposal of congressmen. Write your senator or representative in congress, therefore, for a copy of this work. It is of unusual interest and value this year.

The Adulterated Food Investigation, which we mentioned last week, closed for the present here in Chicago, Friday, May 12. On that date we, with Secretary Moore and Vice-President Mrs. Stow, of the Chicago Bee-Keepers' Association, appeared before the Senate inquiry committee, to testify concerning the adulteration of honey as practiced here in Chicago. The Evening Post of May 12 had the following condensed report of the proceedings, which of course doesn't show nearly all of the testimony given:

ADULTERATION OF HONEY.

The early part of the session was not unlike a convention of bee-keepers. Up to nearly noon the committee was hearing statements from bee-keepers as to the adulteration of honey. George W. York, editor of the American Bee Journal, said to the committee this practice was being carried on at present to an alarming extent. It was not the bee-keepers, he said, who were doing this, but the jobbers almost exclusively. The only adulterant he knew of that was used was glucose, and the fact that the jobbers were resorting to fraudulent methods, in his mind, was ample proof that some legislation is necessary to protect the bee-keepers. The object of adulterating honey was solely for pecuniary purposes. Glucose, he said, was worth probably one cent a pound, while pure honey in the liquid was worth 7 or 8 cents. Only in the liquid form, he thought, was there any adulteration. That honey which is bought in the comb is always reliable, because there is no way for manufacturers to successfully imitate the work of the busy little insects in making combs. Some jobbers, he said, put some honey in the comb into a glass jar and poured glucose over it, giving it an appearance as if the honey had run out of the comb into the jar. The presence of comb in such quantities of liquid honey was in itself, witness stated, ample proof that it had been adulterated, for no "first-class" bee-keeper ever put up liquid honey mixed with the comb.

Senator Harris asked witness if any attempt ever was made to feed bees with glucose in order to make the product larger. Mr. York told of an instance where 300 colonies of bees were taken into Mississippi, and an attempt was made to feed them with glucose. The result was that all died. It would be useless to try this experiment, he said, because bees would not eat glucose to any great extent.

NO PRESERVATIVES ARE USED.

Witness said no preservatives were used in honey: that there was a great possibility of honey granulating, but so far as he knew there was nothing done to prevent this, excepting to abstract the honey from the comb and put it on the market in this form. He quoted a statement from one of the adulterators of honey, who said the honey he put on the market for his customers contained seven-eighths glucose and one-eighth pure honey, which he considered really was glucose adulterated with honey, rather than the reverse; but it was sold as "honey."

The only aid the bees are given in producing honey, according to Mr. York, was the furnishing by the owners of a base for the combs. These manufactured bases are the size of the box which contains the honey-comb, and are placed in the middle of the box to help out the insect, as well as to guide it in making perfectly straight tiers of cells. These bases are made of beeswax, and are perfectly pure,

according to witness. There had been experiments made, he said, with a mixture of paraffine and beeswax, but the former had proved too susceptible to heat, and would not answer the purpose at all.

Mr. York was followed by Mrs. N. L. Stow, of Evanston, who is vice-president of the Chicago Bee-Keepers' Association. Mrs. Stow has kept 80 colonies of bees, and her knowledge of the industry has gained for her the position she holds. Her testimony corroborated that of Mr. York, as also did that of Herman F. Moore, secretary and treasurer of the association, who took the stand after Mrs. Stow had finished.

It is the intention of the Senate committee to print all the testimony they may gather as to the adulteration of all kinds of food, and present it to Congress at its next session, and then doubtless an attempt will be made to enact a national anti-adulteration law. We endeavored to impress upon the committee the urgent need of statutory law against all forms of adulteration, including honey, of course. We hope that our testimony will do good. We were glad of the opportunity to give the committee all the information we possibly could.

Mr. Moore and the writer gathered up about a dozen samples of honey—both adulterated and pure—which we placed before the committee. Prof. Wiley suggested that we forward them to his laboratory in Washington, where he would analyze them and then report.

The Reformed Spelling. Mr. Stenog, in *Gleanings*, has this comment on our spelling-reform effort:

Mr. York spells "burr-comb" with one *r*, but spells *fuzz* with two *z*'s, instead of *fu-z*. Why not go the whole length and spell it cel, wil, be for bee, etc.? The new spelling is certainly misleading when *past* is used for *passed*. A law that was *past* last March has ceased to be a law at that time.

Does Stenog object to going by the dictionary? "Burr" is given as correct spelling in the *Standard*, but "fuz" cannot be found there. There is no objection whatever, "in this locality," to spelling cel, wil, and be for bee, unless it be that some people are so conservative that they prefer to hold on to the old no matter how bad it is. Some printer's ink is wasted in printing cel, wil, and bee. As to passed and past, there's no need of spelling a word wrongly just because it has two different meanings. Perhaps Stenog would like bat spelt with two t's when it has wings, so we will know he is not talking about a ball bat. Most people who have learned how to read, know the sense intended simply from the particular way in which a word is used that has different meanings, tho spelt the same. Of course, Stenog, who writes shorthand, *always* writes "past" for "passed" when taking dictations. Pretty good joke on him, when he criticises a spelling that he uses himself, and must necessarily endorse.

It's a fine thing for *Gleanings* that Stenog isn't several hundred years old, for if he were he would still want to keep on spelling as they did in the 16th century, a sample of which we reproduce here, showing how the first ten verses of the eighth chapter of St. Matthew were once printed:

When Iesus was come downe from the moantayne, moch people followed him. And lo, then cam a lepro and worshiped him saynge: Master, if thou wilt thou canst make me cleane. He putt forth his hand and touched him, saynge: I will, be cleane, and immediatly his leprosie was censed. And Iesus said vnto him: Se thou tell no man, but go and shewe thy self to the preste, and offer the gyfte that Moses commaunded to be offered, in witness to them. When Iesus was entred into Capernaum there cam vnto him a certayne Centurion, beseeching hym and saynge: Master, my seruaunt lyeth sicke at home of the palsy, and is grievously payned. And Iesus sayd vnto him: I will come and cure him. The Centurion answered and saide: Syr I am not worthy that thou shouldest com vnder the rote of my house, but speake the worde, only and my seruaunt shalbe healed. For y also my selfe am a man vnder power, and have sowdeers vnder me, and y saye to one, go, and he goeth, and to another, come, and he cometh; and to my seruaunt, do this, and he doeth it. When Iesus herde these sayngs, he marueyled and said to them that followed him, Verely y say vnto you, I have not founde so great fayth: no, not in Israell.

Mr. R. F. HOLTERMANN, of Ontario, Canada, editor of the *Canadian Bee Journal*, writing us May 11, said:

"The prospects here for honey are excellent, and I do not know that the bees were ever in better condition, or had more favorable weather since the growing season came on."

Dr. C. C. MILLER, of McHenry Co., Ill., spent Monday night, May 15, with us, when on his way to attend the annual convention of the Illinois Sunday School Association, at Decatur. The Doctor was feeling well physically, and is as good-natured and young-hearted as ever. He lost about half of his bees in wintering, owing to honey-dew stores, principally, he thinks. He put 280 colonies into the cellar last fall, so his loss amounts to quite a good-sized apiary.

Mr. FRANK ZILLMER, one of our subscribers and a bee-keeper of Crawford Co., Wis., was recently married to Miss Emily Birchard, of Grant County. The local paper, after announcing the event, remarks as follows:

"The bride is well known to our readers, and has a host of friends who join with us in wishing her and her husband (who is a very successful apiarist) bon voyage thru the journey of life. Mr. and Mrs. Zillmer will remove at once to their new home, where everything is in readiness for housekeeping."

We wish to add our congratulations and best wishes to the happy couple. We trust that their troubles in life may be ONLY LITTLE ONES, that afterward may prove to be blessings.

Mr. J. H. MARTIN—equally well known by his other name—Rambler—says this in *Gleanings*:

"We think we are doing the appropriate thing in Southern California when we have a bee-keeper by the name of Honey; but in the northwest portion of Oregon there is a town named Apiary; also a man bearing the same name."

We wondered when we read the above paragraph whether in that Honey family there were any marriageable daughters. If so, we haven't the least doubt that Rambler knows all about them. He's a great investigator, and would be particularly so when it came to a young lady who is sweet both in name and nature. But to exchange so mellifluous a name as "Honey" for that of Martin or Rambler—I doubt if she could be persuaded. You'd better ramble on, Mr. Rambler.

Mr. R. C. AIKIN, of Larimer Co., Colo., writing the *Progressive Bee-Keeper*, April 27, 1899, had this to say for himself:

"As you already are aware, I am a very busy man, and to add to my many duties, I have just past thru a political campaign in which I was not only a worker, but was on the ticket, and am now 'in for it' to serve our little city as a councilman for the next two years. May the Lord help us to rout every whisky-selling scheme that dares to ply in our midst. We won the election with a full ticket and a round majority."

We wish to extend to Mr. Aikin the heartiest kind of congratulations upon his political success. We hope he and his fellow councilmen will have the courage to enforce the laws they have, and make better ones if they need them. We think the quickest way to educate a community up to the level of good laws, and a desire to see them enforced, is just to enforce them for awhile and thus demonstrate to the people the pleasure to be derived from living in a respectable town or city. It is now 15 years since we lived in a place where the laws were enforced. Here in Chicago it is almost true to say that only the laws that suit the politicians are enforced. No attempt whatever is made to close on Sunday the front entrances to hell (saloons), tho there is a State law that would close them if enforced. And it makes no difference which party is in power here, as elsewhere—both want the saloon vote, and so cater to it.

Painting Queens. Instead of clipping the queen's wings, C. Boesch advises in *D. Inker* to paint her thorax a bright color. That would make it easy to tell whether a queen had been replaced by the bees, and in case of a runaway swarm it would be possible to prove property.

More Wax and Less Honey is somewhat favored by W. A. H. Gilstrap, in *Gleanings*. He gives some figures which seem to show that under some circumstances, instead of extracting and saving the combs to use over again, it is possible it might be better to melt up the whole and get more than twice as much wax.

Density of Buckwheat Honey Varies in different localities, according to a discussion reported in the *Canadian Bee Journal*. Mr. Brown said it was thinner than other honey. Mr. Darling had it average 14 pounds to the gallon, and so thick that he could lift 1½ pounds with a spoon. In a dry season it was said to be thicker than in a wet one.

Importance of Good Queens is urged by J. J. Cosby, who rears his queens by the Doolittle plans and thereby accounts for the fact that his bees in a poor season secured 72½ pounds per colony, spring count, and increased from 80 colonies to 100, while a neighbor with 23 colonies got 56 sections in all, and another neighbor with 60 colonies got nothing, all three apiaries working on the same field. — *Gleanings*.

Bees and Colors.—Elias Fox discusses this matter in *Gleanings*. He gets many stings with black pantaloons, but very few with light ones. A black ribbon or feather worn by his wife is a distinct point of attack. If he wears no

veil, the attacks will be upon the mustache, eyes, eyebrows, or right under the hat-rim, and nine times out of ten a sting on the hands will be near or under the shady edge of the sleeve. A team of horses past his apiary; the white horse escaped with few stings, while the dark bay with black mane and tail was stung to death.

Taking the Travel-Stain Off from the surface of section honey, according to an editorial in *Gleanings*, is a thing that may yet be accomplished. Byron Walker is confident that he has discovered a successful method. If it is true that the dark color of sections is due to bits of old comb brought up from the brood-combs, it hardly seems that the sections can be made white otherwise than by reversing the process and removing the outer portion, a thing that seems hardly possible of accomplishment. Mr. Walker will certainly do a great service if he gives a successful plan.

The Hungarian Bee is praised in *Bienen-Vater* by Maurus. An inexperienced eye cannot distinguish it from the Carniolan. But its flight is different. It goes straight as an arrow, while the Carniolan has a more circling flight. It is grayer than the Carniolan, with yellowish rings and yellowish down. In southern Hungary it is almost as highly colored as Italians. It is more inclined to swarm than the Italian, but less than the Carniolan. It also holds middle ground between the Italian and the Carniolan as to the amount of brood reared. Among the places to which it has been sent are mentioned Illinois, Ohio and Kentucky.

Albinos as to Wintering.—J. O. Grimsley reports, in the *Ruralist*, that the winter in Tennessee was exceptionally severe, the mercury at one time going down to 20 degrees below zero. In an apiary composed of albinos and Italians he reports the loss not so heavy as expected, but says:

"To our surprise it was confined mainly to the albinos. A few light colonies of Italians were lost, and we barely 'saved seed' of the albinos. We were not surprised so much at the loss of albinos, as we expected a greater loss all around, but the test has proven that for the extreme North and severe winters, albinos must be well protected.

Hildreth & Segelken, JOBBER AND COMMISSION MERCHANTS.....

120-122 W. Broadway, **HONEY, Beeswax, Maple Sugar and Syrup.**
NEW YORK.

We desire to inform our friends and patrons that our firm has been re-organized and additional capital added. The business will be conducted under the firm name and style of

HILDRETH & SEGELKEN,

at the old stand, where we have had the pleasure of serving our friends for the past 11 years. Management and supervision will be the same and our business methods—those of square and honest dealings—will be practiced as heretofore.

We believe we have now the esteem and confidence of our shippers throughout the country, and that our dealings, as a rule, have been of the most pleasant nature.

Our additional capital will put us in position to increase our already large business still farther, if possible, and at the same time enable us to treat our shippers even more liberally than heretofore, in making advances, etc.

Records will show that we handle by far the bulk of all the honey sent to our market. We make honey the principal part of our business, are personally acquainted and have trade connections all over the country, which enable us to handle any amount of honey to better advantage than any other house.

Old shippers know us and will bear us out in what we have said. Those bee-keepers who do not know us and have had no dealings with us, we would cordially invite to correspond with us and make our acquaintance. We not only handle on commission but buy largely as well, from small lots to carloads, for spot cash.

We wish to call the attention of the Southern bee-keepers to the fact, that our market never was in better condition than this season. Old stock is disposed of and the market is bare, with a good demand. New crop will find ready sale and at higher prices than have ruled for years past. We would advise them to send their honey, while there is a good demand at good prices, as later on conditions of the market may change.

We also handle **MAPLE SUGAR AND SYRUP** very extensively, and would be pleased to hear from those having any of these goods to offer.

In conclusion, we wish to extend our thanks to all of our shippers for their past favors, and trust to receive their kind consideration in the future.

Root's Column

ENTIRELY UP WITH ORDERS

Our extensive enlargements last fall, costing in the aggregate some \$15,000, enables us to keep pace with our increasing trade. Send in your orders, and they will be promptly executed, either from the main office or branches and agencies. Give us a trial, and see how quickly we can make shipment.

The Farmer.

What higher fate for man can wait
Than 'neath the overarching sky
To sow and reap, to tend and keep
The fertile fields that round him lie?
Small pleasure springs from joys of kings
And richer is his lot by far,
Whose life is spent in sweet content
Where hearth and home and loved ones are.
Farm Journal.

Apiculture Prospering.

I could not help noticing what a change there is in the "Old Reliable;" it seems it is crowded more and more with such valuable information, especially the last two weeks.

Bees are now about getting up to their original working order. Prospects are good for a fine honey year. White clover is beginning to bloom, and locust also in full bloom. Everything pertaining to apiculture seems to be prospering, and if we have a few seasonable rains the bees and we will do the rest. J. WILEY MOUNTAIN,
Anderson Co., Ky., May 11.

Severe Winter on Plants and Trees.

The past winter was perhaps more severe on plants and trees than any other year in the memory of "the oldest inhabitant." Roses called hardy were killed to the ground, altho well protected. Many soft maple trees are badly injured, and I think many ash trees are killed outright. Farmers report that red clover is almost entirely killed, but, somewhat strangely, white clover seems to be uninjured. C. C. MILLER,
McHenry Co., Ill., May 20.

Bad Weather for Bees.

The weather has been very bad for the bees. We have had just a few days that they could work with any comfort. LEWIS LAMKIN,
Woodbury Co., Iowa, May 16.

Bees Wintered Poorly.

Bees wintered very poorly here the past winter. My neighbor lost 60 colonies out of 65. I lost one-half, which is 50 colonies. My bees are now in very good good shape. The American Bee Journal is the boss of all the bee-papers I ever read. OLIVER CARON,
Red Lake Co., Minn., May 14.

Wintered Without Loss.

My four colonies of bees wintered on the summer stands packed in chaff and sawdust without any loss. A. SHAW,
Grant Co., Wis., May 14.

Shake? What's the Use?

Have you ever reflected on the uselessness--nay, the absolute danger attending the usual promiscuous hand-shaking? It is a meaningless custom with the majority of people, in which no sentiment or genuine interest enters. This fact is apparent enough on the mere observation how this perfunctory salutation is accomplished.

Two persons meet who entertain no special regard for each other, but each extends a "flipper" and mechanically shake each others' fingers. What's the use?

But let us consider the more dangerous results that not infrequently occur. Here comes a man with whom you shake. In a week or two your hands begin to tingle and soon you find you have caught the itch! This you generously give to your family and friends to keep them busy scratching. Eczema is often contracted in this neigh-

SWEET CLOVER

And Several Other Clover Seeds.

**THIS IS THE NEW
RUMELY
STRAW BURNING
TRACTION
ENGINE.**

Like all the Rumely engines it is composed of the best material throughout. Designed especially for burning straw but will also burn coal or wood.

Specially constructed boiler, presenting largest heating surface. It is a quick steamer. One of remarkably high power and efficiency, requiring the minimum amount of steam. Five-foot drive-wheels with 16-inch face. An efficient spark arrester prevents all danger from fire. The usual Rumely high finish. We make also other traction engines, portable and stationary engines; the famous "New Rumely Thresher," Horse Power and Saw Mills. All are fully described in our Illustrated Catalogue—FREE.

M. RUMELY CO., La Porte, Indiana.

borly fashion. Nor is that the worst. Here comes an exuberant chap whom you may never have seen, but shake he will. You take hold of his hand in good country fashion, to soon learn what a clammy, slimy thing you've had hold of. May as well shake the tail of a fish. But note that eruption on his hands, and the evil smell he has imparted to yours! If in your enthusiasm you have not thereby contracted a case of syphilis that will cost you \$100 to cure, it has simply been a matter of good luck rather than good judgment.

I have been vexed more than once at my cowardly weakness in not refusing to shake hands with some, when I instinctively desired to go and wash my hands immediately afterward. The nastiness was abhorrent! I have learned, however late, to ignore the extension of an unknown hand to me. I simply don't see it, and go on saying what I otherwise would. This seldom gives offence.

Next to the women's habit of kissing (even women they dislike), promiscuous hand-shaking is the most repulsive.

DR. PEIRO.

Bees Doing Fairly Well.

Bees are doing fairly well. It is very dry, and we have to feed. I have about 300 colonies. **E. H. STURTEVANT, Washington Co., N. Y., May 10.**

Bees in Fine Condition.

My bees never were in finer condition at this time of the year, and I only wish I had been prepared to get some of this fine willow honey in the section boxes.

MATE WILLIAMS.

Wadena Co., Minn., May 12.

Good Prospect for Honey.

It has been rather discouraging so far. The loss of bees around here is about 50 per cent. My loss is three-eighths. North of here there seems to be nothing but beeswax left. Prospect for honey is good.

GUS DITTMER.

Eau Claire Co., Wis., May 12.

Great Mortality Among Bees.

I am sorry to record the great mortality among the bees in this locality. Nearly all the bees have died, fully four-fifths, if not more, have succumbed either to the long, cold winter, or honey gathered from sources that proved destructive to bee-life. I think perhaps both combined may have added to the great loss. What few colonies survived the ordeal seem to be weak, and will need good nursing to bring them thru. I had 38 colonies, part of them in the cellar; out of that number I have three left, and two of them are very weak. All that were left on the summer stands perished. One of my neighbors had about 65 colonies, and he has three or four left, and they are weak. So it is all over this county, so far as I can hear, many having lost all. The weather is against us now, as it is cold and quite rainy. Fruit-trees are in bloom, but are of little account to the bees—too wet and cold for them to be out much. **L. ALLEN, Clark Co., Wis., May 10.**

What I Know About Honey-Dew.

I have seen honey-dew fall more than a score of times, not as dew, but just like small drops of rain, and I have seen it fall on the leaves of the trees and spatter just as a drop of rain will: then the dew at night thus out so that it spreads over the whole surface of the leaves, and while it is damp the bees gather it. They can't gather it when it is dry and hot.

This is not theory; any man can see it for himself if he will take the trouble to step out to some clear place, when there is a heavy flow of it, and look under the sun on a bright, clear evening from four o'clock till sunset. Don't get where there is timber lest you think it falls from the trees. My

bees gather it and I have no more trouble selling it than I do what they gather from flowers.

Now a word about "bug-juice": Has any man taken pains to see which comes first, the bugs or the juice? We see them on sprouts and we see juice also, and if I am not laboring under a great mistake the bugs are only scavengers. I have had two seasons' observation and the bugs were second both seasons. Now I will explain how it was:

There are cherry and plum sprouts growing right in my bee-yard, and when a sprout is very thrifty I see on the tender taps, from six to eight inches down, that a sticky substance exudes from both stem and leaf on the top and bottom, and I have tasted it, and it was sweet, like honey. There was not a living thing on it, but in two or three days I would see some small insects on it, and in three or four more days the whole of the stem and all the underside of the leaf would be black with them.

W. T. ALEXANDER.

Ozark Co., Mo., May 10.

Safe In-Doors—Loss Out-Doors.

Bees wintered in the cellar with but little loss, and are in good condition now. Those left out doors are all dead.

J. N. SHEDENHELM.

Iowa Co., Iowa, May 12.

Honey-Dew on Cotton Swarming.

For some time now there have been several articles on honey-dew in this journal, and the same subject has been commented on during conventions.

I am living in the cotton-belt of Texas, on the edge of thousands of acres of post-oak and black-jack (a species of oak) scrub, and my bees are working hard on the bloom, which affords a great deal of pollen but no honey, or very little.

To counteract the lack of honey in the bloom, there is a little caterpillar about 3/8 inch long, that feeds principally on the

Farm Wagon Economy.

The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

ELECTRIC

This wagon is composed of the best material throughout white hickory axles, steel wheels, steel hounds, etc. Guaranteed to carry 4000 lbs.

These Electric Wheels are made to fit any wagon, and make practically a new wagon out of the old one. They can be had in any height desired and any width of tire up to 8 inches. With an extra set of these wheels a farmer can interchange them with his regular wheels and have a high or low-down wagon at will. Write for Catalog of the full "Electric Line" to Electric Wheel Co., Box 16, Quincy, Ill.

No. 514—Extension-Top Two-spring Carriage. Is complete with lamps, fenders, side curtains, storm apron and pole or shafts. Price, \$63. Guaranteed as good in every way as others sell for \$70.

THE BEST FOR THE MONEY

is what every man is naturally seeking. He should be doubly careful when it comes to the purchase of vehicles and harness. A man's life and that of his wife and family often depend upon quality in his buggy or carriage and harness. We give extraordinary quality for the money. Then there are the advantages of our plan of doing business.

WE HAVE NO AGENTS. but sell all goods direct from our factory at wholesale prices.

We ship our goods anywhere for examination and guarantee everything. We make 170 styles of vehicles and 65 styles of harness. Don't buy any of these things until you get our large illustrated and descriptive catalogue. It's FREE.

leaves of the black-jack, and after it has run its appointed time, it webs itself up in one of the leaves. In eating, it starts generally on the edge, and wherever it cuts one of the laterals running from the mid-rib, there comes a drop of transparent liquid, about the size of a pin-head, which, if left for a day or two, gets as thick as good, ripe honey, is very sweet, and is more abundant after a good, heavy rain—say a week after. I have noticed this for the last two years. My bees suck this eagerly, and boil in and out of the hive in a way that makes me feel good, and tells me that swarming-time is near at hand.

Sometimes, during a damp spell, the cotton gets covered with vast numbers of aphids, and the upper side of the leaves will first get gummy, and then will even drip a kind of dirty-looking sweet fluid. If there is anything else on hand the bees here will not touch it. The same way with the cottonwood-tree, the leaves of which will get in the same condition. This will attract myriads of flies and wasps, but never a bee.

I have a queen that is four years old. I have had her two years. Last year she kept 16 Hoffman-frames full, but this year only 8. Now her daughter keeps 16 frames going. This is what I want to do: When mother and daughter swarm, cut out all but two of the best queen-cells from each hive, and then go to all the other hives, cut out every one of their queen-cells, and substitute two of these others, or my good ones.

Say mother and daughter are Nos. 1 and 2, respectively, No. 3 has swarmed about 10 days ago and is pretty short of bees, as I shook off a goodly number from the parent colony, and drove them in with the swarm on the old stand. Will it make much difference if I kill the young queen in No. 3 when either Nos. 1 or 2 swarm, and give them a cell or two with protectors?

W. H. ALDER.

Callaban Co., Tex., Apr. 27.

[The difference would depend altogether upon the length of time the substituted cell would be in getting a queen to lay after the other is removed. You can measure that pretty closely by the length of time between the swarming of No. 3 and No. 1. If they should swarm at the same time, there would be no loss of time by the change of cells. If No. 1 swarms 5 or 10 days after No. 3, then 8 or 10 days of laying will be lost.—C. C. MILLER.]

Texas.—The Central Texas Bee-Keepers' Association will meet at Milano, Tex., July 29 and 31, 1899. All are cordially invited to attend.

H. H. HYDE, Asst. Sec. and Treas. Hutto, Texas.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, May 8. Not anything of consequence doing; a little honey is being sold at prices that have been prevailing for some time. White comb is scarce, but there is a surplus of dark. Extracted unchanged. Stocks light. Beeswax, 27c. R. A. BURNETT & CO.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10c; dark and amber, 8c. Extracted in fair demand without change in price. Beeswax, 25c to 26c.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey. M. H. HUNT.

NEW YORK, May 9.—Fancy, 70c; choice, 60c; fair, 52c; common, 55c per gallon. Beeswax quiet at from 20c to 28c, according to quality.

Our market is in first-class condition, being bare of extracted honey, and demand good. New crop is beginning to arrive from the South. Comb honey is well cleaned up; some demand for white but demand for dark has ceased. HILDRETH & SEGELKEN.

SAN FRANCISCO, May 3.—White comb, 10c to 10 1/2c; amber, 7 1/2c to 9c. Extracted, white, 7 1/2c to 7 3/4c; light amber, 6 1/2c to 7c. Beeswax, 26 1/2c to 27c.

In quotable values there are no changes to record. A ship clearing this week for Siberia took 231 small cases of extracted, being honey repack by jobbers. There will be a fair yield this season in the San Joaquin, probably 150 cars, mostly all-alta honey, but the production will be very light in the balance of the State.

BOSTON, May 17.—Fancy white, 12 1/2c to 13c; A No. 1, 11c to 12c; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7 1/2c to 8c; light amber, 6 1/2c to 7c. Beeswax, 27c to 28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is bred at this season of the year. BLAKE, SCOTT & LEE.

KANSAS CITY, May 15.—No. 1 white comb, 15c; fancy amber, 14c; No. 1 amber, 13c; fancy dark, 13c; No. 1 dark, 12c. White extracted, 6c; amber, 5 1/2c; dark, 4c to 4 1/2c. Beeswax, 25c. C. C. CLEMONS & CO.

CLEVELAND, March 9.—Fancy white, 13c to 14c; No. 1 white, 12c to 13c; A No. 1 amber, 10c to 11c; No. 2 amber, 9c to 10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & CO.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11c to 12c; some very poor selling at 6c to 7c, and dull. No more business in honey before the opening of the ensuing season. BATTERSON & CO.

OMAHA, May 18.—It is a hard matter just now to give quotations that would have any meaning at all. With the exception of small lots of buckwheat—very good for its kind, but it is not the kind wanted here, which dragged at 8c to 9c—there have been no new receipts, and there will not be a pound of honey carried over in dealers' hands. First receipts of new crop will certainly be picked up eagerly at fancy figures. PEYCKE BROS.

Nuclei of Bees For Sale.

We have arranged with a bee-keeper in Lee Co., Ill., about 100 miles west of Chicago, Ill., to fill orders for 3-frame (Langstroth) Nuclei of Italian Bees, with Queens, in light shipping-boxes, at \$2.75 each, or in lots of 5 Nuclei, with Queens, at \$2.50 each. Address:

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

I ARISE

To say to the readers of the BEE JOURNAL that

DOOLITTLE...

has concluded to sell QUEENS in their season during 1899, at the following prices:

- 1 Untested Queen \$1.00
 - 6 Untested Queens.. 4.50
 - 12 Untested Queens 8.00
 - 1 Tested Queen 1.50
 - 3 Tested Queens..... 3.50
 - 1 select tested queen 2.00
 - 3 " " Queens 4.00
- Select Tested Queen, previous season's rearing, \$3; Extra Selected, for breeding, the very best, \$5.00. About a pound of Bees in a 2-frame Nucleus, with any Queen, \$2.00 extra.

Circular free, giving full particulars regarding each class of Queens. Address,

G. M. DOOLITTLE,

CONTRIBUTED ARTICLES

Bees and Fruits—The Facts in the Case.

BY PROF. A. J. COOK.

As conductor of Farmers' Institutes for Southern California, I have a good opportunity to feel of the public pulse regarding bees, and I have been more than gratified at the general right-mindedness of all parties interested. As a region where all kinds and the most luscious fruits are raised, and where extensive fruit-drying is carried on, it goes without saying that bees will of necessity be more or less of an annoyance at certain seasons in certain years. When we couple with the above facts that of the general presence of bees, and often in immense numbers, we readily see that the question of bees and fruits becomes one of great importance.

The last week in March and the first week in April I held institutes in four regions where fruit-growing is the leading industry, and where bees are kept in great numbers. These meetings were attended by hardly less than 2,000 people in the aggregate. In two of the places, Villa Park and Banning—lawsuits have been recently instituted between orchardists and apiarists. The fact that I was requested to give the true status of the relation of bees to fruit, shows clearly that the people for the most part wish to know the truth. I gave as below the facts as I see them, and was more than pleased to note that few took objection to my position; indeed, only one man called in question my statements, and he did so in private, and not in hostile mien. I am very sure that Southern California will very soon be in the same attitude as the people of France, Italy and England, and will wish the bees brought to the orchards, and not cry for their removal. Already the orchardists in most localities are converted to the right belief.

The following is the position I took in the premises:

It is a truth demonstrated beyond question, by Darwin, and by many other scientists, by our Department of Agriculture, and by my own experiments, that many flowers are sterile to their own pollen, or to that of the same variety of fruit. It is also true that pollination is always necessary to seed-production, and usually to the production of the pulp in case of our berries, pomes, drupaceous fruits, etc. There seems as little doubt but that some fruits usually or sometimes fertile to their own pollen, or to that of the same variety, are under less favorable circumstances sterile to the same. Thus, the Bartlett pear is generally sterile to Bartlett pollen, tho occasionally under favorable circumstances it fruits well tho no other pears are in the vicinity. Yet in these exceptional cases no one knows when the tide will turn, and the Bartlett fail to produce unless other pears are hard by to insure cross-pollination. We are sure, then, that mixing of fruits so as to secure cross-pollination is absolutely essential in almost all cases, to the best success, and in a large proportion of cases to any success at all.

Again, this cross-pollinating requires insects to carry the pollen-grains from the anther of one bloom to the stigma of another. Before the orchards were planted the fruits were less numerous, and the solitary scant-insects were sufficient to do the work; but as we mast the fruits in great orchards, the native solitary insects were all too few, and fortunately the social bees were brought along with the fruits. Even the social native insects, like social wasps and bumble-bees, are very few in spring when the fruits bloom, and so are absolutely inadequate to pollinate our orchard trees. The non-seeding of red clover for the early first crop is because the bumble-bees are too few to properly cross-pollinate the bloom. It is possible that in this case the flowers are fertile to the pollen of other red-clover blossoms but not to their own.

The orchardist then must have the bees. To drive them away would be to kill the goose that lays the golden egg.

Again, bees never attack sound fruit. They only come when bird, wasp, or sultry weather combined with over-ripeness break the rind and cause the juice to exude. Possibly bees could bite open the skin of the fruit, but positively they never do. Yet let the juice once ooze, and then the bees quickly hie to tree or drying-tray and leave little behind to show what once was there.

When we remember that nearly 90 percent of the ripe fruit is juice, and that the bees take this, we see that little would be left. The juice often oozes from very ripe fruit, and so bees are often in the vineyard to the great annoyance of those who would gather in the vintage. Fruit on the trays in the drying-yard has the skin removed, or is cut open, and so the bees may take most of it unless repelled by sulphuring, which is now generally done. We see, then, that bees are a disturbance at times, and annoy the orchardist greatly. Then must the apiarist be driven off? Not so, say the European pomologists. They want the bees, and there is no quarrel between the two industries. Not so, say the most intelligent fruit-men of our own State and country, for we must have the bees to aid us in time of bloom.

What then? It may be wise to move the bees temporarily on rare occasions when the annoyance is most severe. If so, who should bear the expense? Surely, not the bee-keeper, for he was the pioneer in the region, and has a first, or at least an equal, right. The removal is for the fruit-man, and he should be at the most, if not all, of the expense. But each should know all the facts, that bees are never harmful to flowers, but always necessary to best success, and that they are only injurious to wounded fruit; that if they are to be temporarily removed it is for the good of the fruit-man, and he should bear the expense. The harm is usually not great, and the annoyance usually almost nothing, so that if the bee-men and fruit-men donate the one to the other their choicest products, and cultivate good-feeling and not enmity, each may be a tremendous blessing to the other, and all the best of neighbors.

Los Angeles Co., Calif.

Advantages of Docility in Queen-Bees.

BY W. W. McNEAL.

JUDGING from the superior excellence of a queen reared to supersede the old one, I am led to believe that to further domesticate our bees, all queens should be brought up in accordance with conditions as therein found. At such times the desire of the whole colony is in the interests of the home they have. The nurse-bees are not intoxicated with that wild dissipation which culminates in swarming, and which comes from a knowledge of the purpose queens are reared during the flush of the honey season.

To take away the reigning queen when the colony is enjoying a flourishing situation, in the hope of securing a number of young queens, and then expect the mother-bee to duplicate herself in these, it seems to me, is entirely wrong. The colony is thrown into a state of intense excitement and worry, if not frenzy, and more especially is this the case if the bees are blacks, or hybrids, the kind so frequently chosen for cell-builders. Now, surely, the nurse-bees will not, cannot at such times, furnish nourishment that will develop a queen-bee possessing the most steady and pleasing temperament. If queens so reared are allowed to receive their first impressions from angry, loose-footed bees, or bees madly bent on swarming, it would very materially affect their good behavior, and the tie that binds them to home and its sweetness.

I believe it advisable, even when rearing queens in colonies having a laying queen, to remove the combs on which the cells are built to the nursery as soon as they are capt. Then when the queens emerge from the cells their first lesson will be at the hands of the apiarist. I have retained young queens in cages containing honey and comb, away from any but very young worker-bees, and permitted them to take their first flight from my hand or coat-sleeve. They would return, barring calamities that sometimes overtake them while in the air.

If they are handled gently, never blowing smoke or one's breath on them, their action soon contrasts largely with that of virgin queens which have remained in the hive. I see no reason, if one chooses to take the pains, why the mating of queens could not be secured before giving them back to the hive-bees at all. Those large, supersedure queens, when fully developed and on the combs, behave as if they had a realizing sense of being in their proper element, and were fully entitled to protection and respect. Not only are we to expect strong, gentle workers from gentle queens, but more uniform success in introducing them into strange colonies of bees. Any one who has had experience knows that much depends upon the queen being cool-headed and quiet at such times; and in any colony of bees they are much less liable to be balled when it is necessary to manipulate the combs.

Scioto Co., Ohio.

Some Observations on Queen-Rearing.

BY HENRY BOSWORTH.

I AM one of those who believe that we should improve upon Nature in whatever line we may be engaged: and just how is the best way to accomplish this object, is the great secret of success. It has been my good fortune to be engaged in apiculture nearly all my life, and while the occupation has been fairly remunerative, it is not from this cause alone that I have continued in the business.

I am very much interested in the study of the operations of the honey-bee in all its phases, and particularly in queen-rearing, in which I have had some experience, and will give a glimpse of the result of my observations.

First, the colony to do the work should be strong in bees, and, I think, the stronger the better; if not so naturally, it should be made so by feeding, or by supplying bees from some other colony. Many talk about the *swarming impulse*, but I prefer the *business impulse*; and if there is not honey enough coming in to make this impulse, you must secure it by means of feed.

When you have the colony in the right condition, make it queenless, and let it form queen-cells; let it remain in this condition until the larvæ are too old to rear queens from; then overhaul and destroy all queen-cells, which will put the colony in the right condition to rear queens from eggs that you may supply. To obtain the eggs for this purpose, I place an empty comb or two, or more if desired, in the center of the brood-chamber of my best breeding queens two or three days before I wish to use them in the prepared colony. When the queens are all started from the egg, they will all hatch about the same time, and you may expect that they will be ready to cut in about 14 days; or you might wait a little longer.

I now divide the colony into which the combs with eggs have been introduced, into nuclei—one or two frames each—and insert one of these newly-formed queen-cells in each nucleus. If there are enough cells to supply the demand, I make the nuclei but one frame each; and if there are more cells than frames, which is often the case, take frames of comb and brood from other hives. Make the nuclei in the afternoon; shut the bees in until the next morning, then liberate them, and but few will go back to the old hive. I want brood in each nucleus, and before the queens are ready to take their "wedding flight," they should be supplied with unsealed larvæ.

Geauga Co., Ohio.

When to Put Supers on the Hives.

BY C. P. DADANT.

A BEGINNER inquires as to the best time to put on the supers, and how he can ascertain what colonies are likely to need them, as he has been told that it is a mistake to put supers on a hive when the bees are unlikely to be able to put honey in them.

The time to put on supers, whether for extracting or for comb honey, is just before the beginning of the real harvest or at its very inception. When the harvest is about to begin, or is beginning, the least delay is injurious, as the possible lack of room may cause preparations for swarming on the part of the strongest colonies, and it must be borne in mind that these colonies are the ones upon which we should depend for the best of the crop.

In this, and other States near us, it is of no use to expect a flow of honey sufficient for surplus before the blooming of the white clover. There are exceptional cases in which the fruit-bloom has produced a surplus, but I believe that, if such cases could all be reported, we could still count them on the fingers, every year, in Illinois. So it is of little purpose to worry about getting ready for the crop until the white clover gets into pretty full bloom and the weather is satisfactory. I have seen—and so have probably a number of our readers, among those who have had practical experience—I have seen the bees starving, actually throwing out their brood, early in June, while the pastures and meadows were turning white with the abundance of the bloom, just because of a few cold, rainy days. The hives being very populous, and having a great deal of brood in all stages, and a great many young bees hatching daily, the consumption of stores is rapid, and a bad turn in the weather makes it imperative on the apiarist to closely watch his colonies. Even with a plentiful bloom and seemingly fair weather for honey, there is sometimes such delay in the crop as to disappoint the eager bee-keeper. The causes of a production of honey in the calyx of the flowers are a

mystery to us all, so we are still unable to ascertain, otherwise than by an ocular examination of the hive, whether the bees are getting much of a surplus.

The first signs of a beginning of the crop are detected by the whitening of the combs by the bees. The harvesting of a little honey prompts them to repair the combs that have been cut down by the unsealing of the cells that contained the previous crop, and they hasten to repair these and add fresh wax to them, just as soon as they feel that there is enough surplus produced to justify them in using a part of it in that way. Even the blackest and oldest combs are usually refreshed, and at the first signs of this evident encouragement one should lose no time in putting on supers on all hives that show it. The fresh honey itself might be detected even a day or two sooner if the combs are lifted out, for it drips out just like water, being thin and unripe.

We would put extracting-supers on every colony that shows whitened combs, but the comb-honey supers ought to be withheld from such colonies as have not yet filled all their combs with brood, unless such combs be removed and the space be reduced with a dummy or division-board; in which case the space over the brood may be supplied with supers.

When we run for extracted honey it matters but little whether the bees still have room in their brood-chamber when we put on the supers. Unless the weather is cool, and the space added is entirely too extensive, there is no drawback to the supplying of the hive with a liberal amount of empty combs. With large hives and populous colonies in very bright seasons, we have placed on two supers at one time, giving room for 120 pounds at one time to the best colonies. It is a fact that a very populous colony, in exceptionally good seasons, can fill two supers in an incredibly short time. In 1884 we had colonies with three tiers of supers which were emptied and again filled five times over. This was from the fall crop. In the season of 1889 we extracted three times, during the clover bloom, from a number of colonies that were supplied with three supers.

When running for comb honey, if the supers are put on a hive which has unfilled combs below, we need not look for any surplus until those combs are all filled. Such colonies would better be used for increase. It is our method to take the honey crop from the strongest colonies, and obtain our increase, whenever any is wanted, from the colonies that cannot be expected to yield any surplus. This will be the subject of another article.

Hancock Co., Ill.

Keeping Down the Swarming-Fever.

BY MRS. L. C. AXTELL.

PUTTING on sections early seems to keep the swarming-fever down more than anything else we ever tried. Put them on as soon as it can be done without chilling the brood and retarding brood-rearing. One year, when we had not kept bees many years, we put on the supers, but gave only a few sections in each super, intending to put them on as soon as was needed, but the bees became crowded suddenly, and swarming was fearful; they swarmed over and over again—no time to get the supers filled, so many swarms to care for. So we have learned also to have supers all filled, for a super can as easily be put on as only a one-pound section.

Large entrances in hot weather are a help to keep down swarming, and to keep bees working right along in the supers. With our hive we often (if the hive is in the sun) take down the front side of the hive, or the east side, leaving up the division-board that is at the side of the combs, and is raised from the bottom-board the height that the brood-frames are raised, as we use the Quinby style of hive, and the frames rest on the bottom-board.

Also, we think that bees swarm worse with the use of separators than without, and so we have not used separators for a number of years. Some of the combs are not quite so straight and even, but we have no trouble to sell all the honey we can produce. The greatest trouble, of late years, is that they don't store honey as they formerly did. Every year we hope for the better.

AN EXPERIENCE IN HAULING HONEY.

Some years ago a young man helping us with bees went over to our out-apiary and extracted about two-thirds of a barrel or so of honey. He laid the barrel on its side in a wagon, and wedged it up so he thought it would not turn over and roll about. As it was late he drove pretty fast, and when he got half way home a man called to him and

wanted to know what he had in his wagon. His first thought, the young man said, was to answer back it was none of his business, and drive on, but he answered, "It is honey," and the stranger told him it must be spilling out. The young man looked back, and there the barrel had turned partly over, and was pouring the honey out of the bung-hole into the wagon-bed among the straw, and it was leaking in a stream thru the wagon-bed. He saved some of it, what he could, in pails he had along for feeding-back, and righted up the barrel, as it was not quite all spilled out.

Warren Co., Ill.

Planting for Honey—The Clovers.

BY F. A. SNELL.

AT the close of fruit-bloom, at latest, the surplus receptacles should be in readiness for the crop of surplus honey which will usually come in with the opening of the white and Alsike clovers. Bee-keepers should see to it that all available space along roadsides and fence-corners is occupied with white, Alsike or sweet clover. Our pastures for stock should be well seeded with white or Alsike clover, or a mixture of these seeds. The pasture thus afforded gives an abundant amount of food, and that of the very finest quality for cattle, sheep or hogs. For the dairy it is an established fact, as it has been fully demonstrated, that a greater amount of milk will be secured from pasture of either white or Alsike than from red clover.

In an experience dating back into the 60's, I have tested and observed quite closely as to the Alsike. My first pound of Alsike clover seed was bought in 1867, at a cost of one dollar. The seed was sown, and the little plot was a mass of bloom the following season, and I was much delighted with the plot, its beauty and utility. The bloom was covered with bees to an extent I have never seen surpass anywhere or any time. From this early planting I have handled this clover as pasture and hay, up to the present time, or 31 years.

I may mention right here that in pasturing upon either white or Alsike clover, I have never known any trouble from cattle bloating, as is often the case when pasturing on red clover. The hay from Alsike clover is of the finest quality, and is relished by all stock. The stalks are fine, and not woody like red clover hay, so it is all eaten. This clover may be grown alone for seed or food, or sown with timothy; when with timothy the latter prevents the clover from lodging to quite an extent. In good seasons I have harvested three good loads of Alsike hay per acre. This clover seeds at first blooming, and yields well in seed, which usually brings a good price. As honey-plants the white and Alsike clovers are unsurpassed, and every farmer bee-keeper should grow all that can be used to advantage on his farm.

There cannot be too much done to give us a full bloom for our bees; with the bloom secured, good crops of honey may be had, but if we are negligent we hardly deserve such.

If the Alsike is mown when just out in bloom, it will bloom later in the season, and thus prolong the honey-flow, which might be desirable when the white clover bloom is profuse earlier. The Alsike is very hardy, and will winter well when red clover is killed out almost wholly. I have never known the Alsike to winter kill in the 31 years that I have had experience with it, which is quite the opposite to red clover, as any one of experience knows. Bee-owners can and should induce their neighbors to grow this useful plant.

In many localities white and Alsike clover bloom is the only source from which a surplus honey crop is secured, and too much effort cannot be made to secure their growth. The fertility of the land is improved by the growing of clover, which is also of importance to the farmer. The basswood bloom, where that tree is grown, follows that of the clovers, or comes in before the clover bloom ends—in our latitude, from June 25 to July 5.

Of all the honey-producing trees we have, the basswood takes the lead. When conditions are favorable the yield from its bloom is immense. The honey this tree affords is in quality not equaled, according to my taste, by any other tree or plant. The planting out of the basswood tree along streets, highways, and in groves on our farms, has been sadly neglected. It is high time that all bee-keepers who can do so should be doing this work. Our groves are disappearing at a sad rate, and if nothing is done in this direction soon, many of us who have in the past secured good crops of this fine honey will have none at all, which means a good deal, as in some seasons it has been our early

bloom that gave a surplus. By early is meant during our summer season, in this case.

Sweet clover is an important honey and pollen producing plant, and is well worthy of culture. There are hundreds of acres in every township where worthless weeds now grow, that could be sown to sweet clover, and be of much value to apiarists at least. The farmer bee-keeper would be well rewarded by sowing this for his bees and stock. When stock are turned on it to pasture when young it is fed down and thus kept tender and sweet for the entire season. Were enough sweet clover grown near an apiary the crop of surplus honey from this source would, with good weather at blooming time, pay a nice profit. With us not very much is grown, but it helps to keep up brood-rearing. In some localities it is quite extensively grown, and good crops of honey realized. All who can do so should extend their planting of the sweet clover.

Carroll Co., Ill.

Italian Bees' Honey vs. that of the Blacks—Bee-Pasturage.

BY G. H. ALLEN.

I WAS greatly amused when I read Mr. Bates' article, on page 19, on "Why Italian Bees Store Better Honey than the Blacks," and more so when "Stenog," in *Gleanings*, went so far as to say that it is pretty hard to prove he (Mr. Bates) is wrong, and follows with a long train of reasons. However, I think Cogitator, on page 82, gives the article about its right weight when he admits that Mr. Bates has made some headway, but concludes by saying, "Now, if some one will tell us why black bees store better honey than the Italians—why, then we'll have a mitten on each hand." Now, I am not going to put that mitten on the other hand, but just want to have my say from a practical stand-point, and leave the theory to Mr. Bates and "Stenog."

I commenced to keep bees in 1890, all blacks. In 1891 I introduced Italian blood, and since then I have had blacks, Italians, and almost all grades of hybrids, with a sprinkle of Carniolan blood. Now when the honey is captured before extracting there is no difference in the honey of either strain or mixture. I have never succeeded in getting pure Italians to finish up comb honey equal to the blacks, in color. The Carniolans were fully up to the blacks, and usually high-grade hybrids do first-class work.

EXPERIENCE WITH HONEY-PLANTS.

But there are other questions which interest me more than the above, which are discussed in the "Old Reliable" from time to time, and none more so than pasturage. I will give my experience with a few of the leading honey-plants. I have tried crimson clover for three seasons, and for this section it is a success, and coming just after fruit-bloom it has proven a great boon to my bees. I practice sowing in corn at the last cultivation, or with buckwheat. I prefer to have it sowed from June 20 to July 1, as it is not so liable to winter-kill sown this early; but I have sown as late as Aug. 15, with a good stand the following spring.

Sweet clover yields abundantly here, but grows successfully only on rich land. (I am just out of the lime-stone belt.) I find the seed propagates best when sown during the winter, and when thus sown it will hold its own in all waste places, provided the ground is rich. Italian and sweet clover I have made pay from a dollar-and-cent point of view.

I have realized considerable satisfaction in experimenting with a few other honey-plants. Alfalfa is a failure here, growing luxuriantly until commencing to bloom, when it turns yellow and dies; if cut, it will start up green again.

Spider-plant yields abundantly if the weather is just right, but the care in raising will outweigh the profits.

I failed to mention Alsike in the above, for aside from its honey I would not think of discarding it, for here in mixtures with other grasses it is fully equal to the red, while as a honey-plant it has no equal in this section, except cottonweed, which here exceeds linden in the amount of nectar secreted, when linden is at its best, and is a much more certain yielder, with a longer period of blooming. I have wondered why it is not more spoken of as a honey-plant; probably it does not yield in all sections as it does here.

Pleurisy-root yields scantily here, while Mr. Heddon prizes it highly as a honey-plant.

Monroe Co., W. Va.

Foul-Brood Germs—Spores and Bacilli.

BY THOS. WM. COWAN.

I HAVE read the correspondence respecting the destruction of foul-brood germs contained in honey, by means of boiling, and it appears to me that, when giving advice with respect to such a destructive enemy as foul brood, we cannot be too cautious, and had better err on the side of safety than the reverse.

From the promiscuous manner in which many talk about microbes, bacilli, spores, or germs, it is quite evident that they do not realize that a very great difference exists between them; and conditions that will be destructive of the one may not have the slightest effect on the others. In respect to the particular organism with which we have to deal in foul brood; viz., *Bacillus alvei*, we have to contend with it in two different forms and stages of life, in one of which the vitality of the organism is easily destroyed; while in the other the same organism, but under a different form, is capable of retaining life, and germinating into the condition of the previous stage, even after what would appear the most damaging influences, such as long lapse of time, drying, heat, cold, and chemical re-agents. The bacillus condition is the first stage of active life of this organism; and it remains in this state, splitting and multiplying as long as it has nutrient material to live upon, and other conditions are favorable. A bacillus is rod-shaped, and when, in process of time, it has attained full growth, it splits in two, each of these taking up an independent existence, and going thru the same process; and as it has been shown that as many as two generations can be reared within an hour, and as the same rate of progression can be kept up by each individual in suitable nutrient media it is not astonishing that foul brood spreads rapidly.

Now, while in this bacillus stage it is not difficult to kill the organism (a temperature under 100 degrees Fahr. will do it), and there are a number of chemical re-agents which even in great dilution will destroy bacilli. It is, however, very different in the subsequent stage of existence of this microbe. When the bacilli, or rods, have multiplied to such an extent as to exhaust all the nutriment upon which they were feeding, or come in contact with surroundings inimical to their active existence, the rods gradually turn into spores. At a certain point of the rod a bright speck appears, which gradually enlarges at the expense of the protoplasm in the rod, until in its fully developed state it assumes an oval shape. The sheath swells, and the bacillus looks much thickened; then the sheath breaks, and the spore becomes free.

Now it is when the rods have become spores that the danger arises, because it is very difficult to make many understand the great difference between them and bacilli. They are analogous to seeds of plants, altho they differ from these in possessing greater vitality. Spores retain the power to germinate into bacilli after the lapse of long periods; and Dr. Klein, one of our great authorities, says, "There is no reason to assume that these periods have any limit." We have, at any rate, had ample evidence in our own experience to show that spores have retained their vitality for many years. These spores are not only capable of germinating into bacilli after a long period of time, but will endure heat, cold, drying and chemical re-agents influences that would be destructive to bacilli themselves. The temperature of boiling water does not destroy them unless considerably prolonged, altho a very much lower temperature, as I have already stated, will kill bacilli. If we had to do with bacilli only, in every case bringing up the temperature to 212 degrees Fahr. would be amply sufficient; but with spores it is different. A few minutes boiling will destroy some, because all the spores have not the same degree of vitality; and in this they resemble seeds of plants. It is well known that some seeds will germinate much sooner than others, and some will not germinate at all.

Experiment has shown that, to destroy all the spores, prolonged boiling is necessary, or they must be subjected to a higher temperature, such as is obtained from steam under pressure. Spores are unable to withstand steam, even for a few minutes, at a temperature of 212 degrees Fahr.; but this could not be applied to honey, as the spores would have to be separated before they could be acted upon by the steam.

I have had frequent demonstrations that many do not really understand what boiling, from a scientist's point of view, is, and that is why the results are frequently so different. They are content to think that the liquid is boiling if they see it bubbling, whereas the bulk of it may be sev-

eral degrees below the boiling-point if stirred and thoroly mixt, and, of course, the larger the quantity the longer it takes to raise the whole mass to the boiling temperature. Experience has shown that it is not safe in every case to depend upon 10 or 15 minutes' boiling. Several boilings would be better, but not so convenient to the ordinary bee-keeper. The rationale of this is that, at the first boiling all the developed bacilli are destroyed; then suppose a nutrient medium and other favorable conditions to exist in the honey, the unaffected spores would germinate into bacilli, and could be destroyed in the next boiling. A third and even a fourth boiling might be necessary to destroy the remainder. Failing this method of procedure it is safer, with our present knowledge of the behavior of spores, and taking into consideration the appliances at the command of the average bee-keeper, to insist on prolonged boiling.—Gleanings. April 18, 1899.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY HERMAN F. MOORE.

[Continued from page 291.]

Mr. H. S. Jones, of this (Cook) County, followed with another paper on the same subject as that of Dr. Mason, viz:

How I Handle My Bees in the Spring.

To begin with, they get little handling by me in early spring. No doubt it was intended that I should give my experience in managing my bees in *early* spring. I must start from the close of winter, then if you will follow me thru until spring you will have my whole management.

In the first place, I must describe the hive I use. I make all my hives by hand, buying the lumber in boards, and make it complete from bottom to cover. My hives are all double-wall, without any air-space between, and painted on the outside. You will no doubt ask why I make a hive thus. Because the moisture from the bees is taken up by the inside board; the outside board being painted, warms the inside quickly; the inside board being connected to the outside by direct connection conveys the heat to the inside much quicker.

I winter my bees on the summer stands without any protection, such as fence, etc., until along in January, when I commence to shelter and start the spring managing. On sunny days I open every hive, loosening the packing, which is excelsior, so that the sun goes direct into the super. I watch the sun very closely, in case it should cloud up.

The hives are at once packed and covers put on. This is continued until along in April, according to the weather. Now it is time to examine all colonies, and give them clean houses. We all want clean houses in springtime, so do the bees. I have several new hives on hand, dried and painted. Starting at one end of a row I take out the frames and note their condition, jot it down in my book, opposite the number of the hive. At a glance I know just the condition of that hive; if short of stores I can give sealed or unsealed honey, as the case may demand, and pack them good and warm.

Why should not bees treated thus give good returns for trouble taken? I always give where needed new worker-comb; this will insure larger and stronger bees. Mr. York, when at my apiary last year, noticed how large my bees were. That is the way I got them.

Sometimes I spread the brood, but not unless it will stand it. I do not advise spreading except under very favorable signs; sometimes I stimulate by feeding honey. Bee-keepers should have enough extra combs on hand for times of need.

As soon as possible after the middle of April I replace all old queens with young ones. In this way there is no loss of time, and the bees are not so liable to swarm. I keep very close watch of all colonies, to see that their little wants are supplied promptly.

The extra-strong colonies I divide early in May, giving one-half a young queen, and nurse them along until bass-wood bloom or sweet clover, when they are ready for busi-

ness. I give my bees more care during the early spring than at any other time of the year, because this is the time they need more, and in doing this I am looking after my own interests.

In the first three months of winter there is always plenty of bees in a colony prepared for winter, and as the winter advances they get less in number; after the first of the year they will not be so strong, therefore they need more protection, and some shelter, which must be given if wintered out-of-doors. I take out the packing, according to the weather, until it is all taken out. Then they are ready for supers. I remove the Hill's device and take a good, sharp scraper and scrape all propolis from the tops of the frames. Now the bees are ready for the harvest.

Cook Co., Ill.

H. S. JONES.

Mr. J. T. Hammersmark then opened the discussion in an interesting manner as follows:

How I Handle My Bees in Early Spring.

Because I am interested in the bee-cause, and not believing in simply being a drone in the hive of bee-keepers, but rather a worker, therefore have I accepted the invitation to write an essay on the subject.

In our line of business we all know, or at least we all should know, that to set certain dates for the accomplishment of certain duties about the apiary is an impossibility, for the reason that our work must be done when the weather is suitable, and when the bees can fly. The first thing that I should do with my bees in early spring would be to assist them to clean up their house, no matter whether they were wintered indoors or on the summer stands. During the winter months the older bees die off, and if they do not become clogged up between the combs in their descent, they fall to the bottom-board, which, by the time spring comes around, generally becomes thickly covered with these dead bees. Bees also sometimes die in patches on the comb, caused by their leaving the main cluster on some mild day. But the weather suddenly turns very cold, and they cannot get back to the main cluster where they can keep warm, and are therefore soon chilled thru and die. These and all dead bees should be brushed off the combs, and the cemetery below them should be removed and a clean, fresh bottom-board put in its place. All this is a great help to the colony, and it seems to appreciate this help, for one so treated will build up strong in numbers very much faster than one not so treated.

I would now, should I find a weak colony unite it with a stronger one, so that the two would make one good colony. Feeding the bees with sugar syrup, or, better still, full or partly full combs of honey, is also now in order, for we must see to it that there is plenty of honey in the hive so that the bees shall not be saving of food, and thereby limit the queen in her work of egg-laying, for she must eat plentifully in order to lay eggs profusely. Then the larvae also have to be fed, and the bees themselves have to live, so you see it is very important to have plenty of honey in the hive all the time.

If any colonies are found to be queenless at this early investigation, they should be given a queen, or a comb containing brood and eggs from another colony, from which they can rear a queen. A sharp lookout should be kept on these queenless colonies, as they are liable to be robbed at any time now.

I do not believe it pays to try to build up weak colonies the first thing in the spring, but unite them, and in a short time you can divide them to advantage, if you desire to increase your stock of bees.

In April, when the state of the weather permits, I would cut out all surplus drone-comb. We can leave this work until a later period, but see what our neglect will cost. The queen wastes her time and energy in laying these eggs; the bees waste their time and your honey in nursing and caring for these big, worthless babies. But this is not all, for you must have a hand in this matter also, and cut out this mussy mass of worthlessness if you want the best results in honey. Had I a colony whose population had become so decreased during the winter confinement as to be able to care for say only four combs, I would take the surplus combs away and follow up these four combs with a division-board, for by this change they could keep much warmer, which would also induce the queen to more vigorous egg-laying. When needed, these surplus combs should be given back, one or two at a time, moving the division-board back each time until their regular set of combs are returned, then the division-board should be removed from the hive.

Water placed about in the yard in small wooden tubs with some sort of a float in them to save the bees from drowning in the water is, I believe, of great importance, for on cold days when the bees can barely fly, they can get their supply at home without flying away to find a drinking place. Also, to supply them with rye-flour before they can gather pollen is of some use. But I do not think this is as necessary as the water question. The entrance of the hive I would keep contracted down to an inch or two, as this will help to retain the heat which is of so much value just now. When the weather becomes warm and settled, then these blocks or sticks should be removed, and full entrance be allowed.

As the topic of this essay calls for *early* spring management, I shall not proceed any further, but will leave you right at this point to finish the season yourself. To the bee-keeper, what I have said is old, and experience that he should have gone thru; but if the novice or any one else shall derive any benefit from this paper, I shall not consider it work in vain. A great deal more could be said on this subject, still if what has been read in your hearing is followed out in deed, you are on the right road for strong colonies by the first of June, and all ready, so far as bees are concerned, for the big honey crop in 1899—if it comes.

Cook Co., Ill.

J. T. HAMMERSMARK.

A general discussion of the topic followed, by Dr. Peiro, Dr. Miller, C. Beers, H. M. Arnd, Mrs. Stow, Mr. Hogge, and others.

The next number was a bee-song by Ferdinand Moore, the little son of the secretary, which was well received and applauded.

[Concluded next week.]

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Splints for Stiffening Foundation.

Where can I get, or how can I make, the splints for stiffening foundation in the frames? MINNESOTA.

ANSWER.—I got mine from the A. I. Root Co., but any manufacturing establishment that has machinery for slicing separators can make them. The ordinary wood separators are cut into the proper length, the thickness being 1-16 inch, then a bunch of them can be sliced into 1-16 splints. The first I used I sliced out of separators with a pocket-knife, but that's a slow way.

Fastening Foundation in Frames.

DR. MILLER:—I see in *Gleanings* for Dec. 15 an article about sticks in frames for fastening the foundation. 1. Please let me know the size. 2. Will these answer for extracting without any wire in frame? 3. In speaking of the engraving under No. 1, "half bottom not yet nailed on," does this mean that there are holes in top and bottom bars for insertion of the sticks? 4. How are the sticks imbedded in the foundation? 5. Which foundation, "medium or light," is best? W. C. MYER.

1. The length is $\frac{1}{8}$ inch less than the inside measure from top to bottom bar, and the sticks are 1-16 inch square. The reason for having the sticks $\frac{1}{8}$ inch shorter than the space between top and bottom bar is that it is easier to handle the shorter sticks in putting them in; and, besides, basswood (of which timber the sticks are made) increases in length as well as thickness when it swells, and when the wood is thrown into boiling wax I think it likely that it increases in length.

2. Yes, I extracted about 300 pounds from such combs

that had been built the same summer, and there was no trouble.

3. No. The sticks do not necessarily touch either top-bar or bottom-bar, and there are no holes to let them in. The object of having the bottom-bar in two pieces is to allow the foundation to go between the two parts. The foundation is cut $\frac{1}{2}$ inch wider than the inside depth of the frame. That allows $\frac{1}{4}$ inch at the top to go into a saw-kerf in the top-bar, and $\frac{1}{4}$ inch at the bottom between the two parts of the bottom-bar. The foundation is cut so as to make a close fit to the end-bars at each side, the frame is put on the board, such as is commonly used for putting foundation in frames; the foundation is split into the saw-kerf of the top-bar, and then the second part of the bottom-bar is put in place, a single small wire-nail is driven at the middle to fasten the two parts of the bottom-bar together, and then the remaining nail is put into each end of the bottom-bar. Top-bars and end-bars are $1\frac{1}{8}$ inches wide, and each part of the bottom-bar $\frac{1}{2}$ inch wide. That allows $\frac{1}{8}$ inch between the two parts of the bottom-bar for the foundation.

4. If you put in the dry sticks, the bees will gnaw them out every time. Put a little bunch of the sticks in melted wax, keeping the wax where it will stay hot. At first the air and moisture in the sticks will make a great frothing, and you will not imbey any till all settles and becomes clear. Then with a pair of tweezers, or something of the kind, lift a stick out of the wax, lay it in place, and press it into the foundation with a presser made of a little board about as long as the sticks, or not quite so long, and about $\frac{1}{8}$ inch thick. The edge that presses in the sticks must be kept soakt in water, so the wax will not stick to it. Five sticks are used in a frame, one about an inch from each end-bar, the other three at regular intervals. In rare cases I've had the bees gnaw at the sticks, even when cookt in wax, but I don't know why.

5. I have used rather heavy foundation (some I've had on hand for a number of years), but it may be that light foundation would do just as well. Certainly just as light foundation can be used as if wire replaced the sticks.

These sticks allow the combs to be built solid to the bottom-bar (but sometimes the bees will dig under), and I know of no advantage in any way that the wires have over them.—Gleanings.

Blacks vs. Italians as to Hardiness.

Are Italian bees as good to stand the cold as blacks? I had five colonies Italianized last year, and they all died. I had 15 colonies of blacks, and lost one; they were all in one row in double-walled hives. A good many bees died in this county the past winter.

NEW YORK.

ANSWER.—I don't know whether Italian bees, taken as a whole, differ in hardiness from blacks. It is quite likely that *your* Italians are not as hardy as *your* blacks. But you must remember that all blacks are not alike as to hardiness and other qualities, and also that Italians vary.

Pink Comb and Honey.

Why do bees build pink comb and store honey of the same color in the brood-frames? Some of the combs in our city hives are thus colored.

MARYLAND.

ANSWER.—I don't know what plant they are working on to produce such results, but it is well known that the color of the honey, and to some extent the color of the comb, depends upon the kind of flowers visited.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 50 cents; 50 for 70 cents; 100 for \$1.25; 250 for \$2.75; 500 for \$4.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Blocking Up in a Hot Climate. In Gleanings, J. K. Hill, of Texas, says he has been troubled every year until the past year with combs melting down in hives standing in the sun, there being a $\frac{1}{2}$ -inch entrance the whole width of the hive. Last year he put a $\frac{1}{2}$ -inch block under each corner of his hives and never lost a comb. Only 2 swarms came from 125 colonies, whereas in previous years swarming had been very troublesome.

How Should Frames Run? At the Ontario convention the great majority preferred what is called the "cold system," with the frames running toward the entrance. One reason was that the hive could be tipped forward so water would run off, also so that late honey for winter would be stored at the back end, and Mr. Hall wanted the back end of the hive at least four inches higher than the front, so that it would be warmer. Canadian Bee Journal.

When to Put on Sections. In the Canadian Bee Journal objection is made to leaving colonies without sections till after the harvest has commenced, thereby inducing the bees to swarm, and it is also objected that in some cases mischief is done by putting them on before the light honey comes, having dark honey in the center of a section. Some advise putting on extracting-combs to catch the first flow of dark honey, then giving sections when the light flow starts.

To Keep Pollen Out of the Extracting-Super was discussed at the Brantford convention reported in the Canadian Bee Journal. One way was to keep the queen out of the extracting-super, but it is not so clear just what was meant by Mr. Armstrong saying, "The queen will not be able to go thru the excluders loaded with pollen." Mr. Atkinson thought there would be no trouble if two stories were allowed for brood. Mr. Alpaugh thinks there is less trouble if the super combs are well drawn out.

As to Amalgamation, Stenog, the gleaner of "Pickings" in Gleanings, says:

"Touching the union of the 'Association' and the 'Union,' Mr. York well says, 'The door is open for the Union to come into the Association whenever it decides to cast in its lot.' That's it. One of the associations must simply cease to exist, and its members be incorporated in the other. Those who are trying to unite certain other organizations nowadays would do well to read Mr. York's words. The only way is to find the best, and annihilate the others by disbanding in favor of the better."

Handling Hoffman Frames. The editor of Gleanings refers to an article in American Bee Journal for April 6, by C. Davenport, whom he styles "one of the most practical writers in all beedom," and commends the tool by which Mr. Davenport handles his frames so well. One feature that was not mentioned, is that of handling two or three frames at a time, whereas with loose-hanging frames each frame must be lifted out separately. Mr. Root thinks this an important matter. He disagrees with Mr. Davenport as to the edges of the end-bars, preferring the V edge to the plain.

Large Frame Hives vs. Two-Story Hives.—A. N. Draper discusses the matter in Gleanings. He quotes Langstroth Revised as saying that the Quinby frame is too long and the Langstroth too shallow, advising beginners to use a frame as long as the Langstroth and as deep as the Quinby. After having handled as many as 200 colonies in Langstroth frames three stories, and afterward trying the large hives and frames, and especially noting the difference in wintering, he is a strong advocate of the large frame. Mr. Draper challenges Editor Root to make the experiment of having 30 or 40 ten-frame hives the same as the Langstroth, only with frames $2\frac{1}{2}$ inches deeper, agreeing to pay the expense of making them if after three years' trial the editor is not pleased with them.

September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

JUNE 1, 1899.

NO. 22.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Spraying Law of New York came near being repealed, according to reports in Gleanings. W. F. Marks says:

"The opposition stole a march on us, and got practically thru the Assembly before we knew it; but when their bill reached the Senate, thanks to Senator Raines, who was watching for it, it was promptly killed."

Intelligent horticulturists know that there is no need to spray when trees are in bloom, and that harm may come of it, but so long as some of them are not intelligent the law-makers need watching.

Spelling Reform in Chicago Schools. It seems that the effort to simplify English spelling is making some headway these days. We find the following in the Chicago Daily News for May 24, which shows pretty conclusively that the Chicago board of education means to be progressive:

The business office of the board of education has adopted the reforms in spelling suggested by the National Educational Association, and approved of by Dr. Andrews. In recent notices to persons having business with the board, Clerk Sam Frankland and his assistants in the office of Business Manager Guilford have used the new system.

The contractors are now notified in abbreviated words that they must get "thru" with their work on specified time, while business firms from which the board expects to make purchases are requested to send "catalogs" to the

board. All of the words included in the list are spelt according to the new method. The same system has been adopted by the other departments of the board.

The words in the list are: Altho, catalog, decalog, pedagog, demagog, program, prolog, tho, thoro, thorfare, thru, thruout.

Dr. E. B. Andrews, ex-president of Brown University, is the superintendent of the Chicago public schools. We are glad to welcome him and his board of education to the ranks of "spelling reformists." For several years past the American Bee Journal has been aiding in this needed reform, and grows stronger in its conviction that it is pursuing the right course. Others are invited to join in the good work.

Honey and Beeswax.—We find in the 1898 Yearbook of the United States Department of Agriculture, that there was reported last year honey to the value of \$98,504, and 151,094 pounds of beeswax, valued at \$41,827. During the same time there was imported 96,604 pounds of honey valued at \$38,158, and 272,097 pounds of beeswax valued at \$72,473.

The Big-Little-Hive Fight has been in progress for some time, and among the chief disputants have been Messrs. Dadant and Doolittle. A somewhat diplomatic distance has been kept up, however, between these two, until the last number of Gleanings, in which Doolittle clinches close with Dadant, and a somewhat lively tussle may be expected. Both men are able, both men are honest, and possibly both are correct from their own stand-points, and it is probable that a good bit of light may be brought out by them.

How Does the Queen See in the Dark, so as to lay eggs on the opposite side of the comb? is a question that has been somewhat considered. Some have thought there might be something like X-rays which allowed the queen to see thru the comb so as to lay opposite the brood on the other side. A. J. Wright says in Gleanings that the queen needs no light on the subject, that it's the "rays of dark" that the queen works by! The accompanying foot-note gives no sign that the editor has any doubt as to the correctness of this theory, but some of his readers who are not 'way up in the science of optics may desire to inquire what "rays of dark" are. Please turn the light on this dark subject, Editor Root; or would "turning on the light" destroy the "rays of dark"?

New York's Foul Brood Law.—The law relating to foul brood in the State of New York has recently been satisfactorily amended, thanks to the hard work of Mr. W. F. Marks, one of the widest awake bee-keepers, and to Hon. Jean L. Burnett, a hustling member of the State legislature. The amended law reads as follows:

(Chapter 223, Laws of 1899.)

AN ACT to amend chapter three hundred and thirty-eight of the laws of eighteen hundred and ninety-three, entitled, "An act in relation to agriculture, constituting articles one, two, three, four, five, six, seven and eight of the general laws," relative to prevention of disease among bees.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:

SECTION 1. Section eighty of chapter three hundred and thirty-eight of the laws of eighteen hundred and ninety-three, is hereby amended so as to read as follows:

§ 80. The prevention of diseases among bees.—No person shall keep in his apiary any colony of bees affected with a contagious malady known as foul brood; and every bee-keeper, when he becomes aware of the existence of such disease among his bees, shall immediately notify the commissioner of agriculture of the existence of such disease.

§ 2. Section eighty-one of said act is hereby amended so as to read as follows:

SEC. 81. Duties of the commissioner.—The commissioner of agriculture shall immediately, upon receiving notice of the existence of foul brood among bees in any locality, send some competent person or persons to examine the apiary or apiaries reported to him as being affected, and all the other apiaries in the immediate locality of the apiary or apiaries so reported; if foul brood is found to exist in them, the person or persons so sent by the commissioner of agriculture shall give the owners or caretakers of the diseased apiary or apiaries full instructions how to treat said cases. The commissioner of agriculture shall cause said apiary or apiaries to be visited from time to time as he may deem best; and if, after proper treatment, the said bees shall not be cured of the disease known as foul brood, then he may cause the same to be destroyed in such manner as may be necessary to prevent the spread of the said disease. For the purpose of enforcing this act, the commissioner of agriculture, his agents, employes, appointees, or counsel, shall have access, ingress, and egress, to all places where bees or honey or appliances used in apiaries may be, which it is believed are in any way affected with the said disease of foul brood. No owner or caretaker of a diseased apiary, honey, or appliances shall sell, barter, or give away any bees, honey, or appliances from said diseased apiary, or expose other bees to the danger of said disease, nor refuse to allow the said commissioner of agriculture, or the person or persons appointed by him to inspect said apiary, honey, or appliances, and do such things as the said commissioner of agriculture, or the person or persons appointed by him shall deem necessary for the eradication of said disease of foul brood. Any person who disregards or violates any of the provisions of this section is guilty of a misdemeanor, and shall be punished by a fine of not less than thirty dollars, nor more than one hundred dollars, or by imprisonment in the county jail for not less than one month, nor more than two months, or by both fine and imprisonment.

§ 3. This act shall take effect immediately.

Hurrah for New York bee-keepers! They went after it and got it. Illinois bee-keepers went after it too, and—"got left." Well, we hope that some day Illinois will have a legislature that will respect the rights of the people a little more, and do justice to so worthy a class as are the bee-keepers of this State.

The Georgia State Fair, to be held at Atlanta, Oct. 18 to Nov. 4, 1899, proposes making quite a feature of the apiary department. The following is the premium list offered on bees, honey, etc.:

| | 1st. | 2nd. |
|--|------|--------|
| Comb honey, quality and manner of putting up for market to be considered..... | \$13 | \$6 00 |
| Extracted honey, quality and manner of putting up for market to be considered..... | 13 | 6 00 |
| Beeswax, not less than 20 pounds..... | 7 | 3 00 |
| Italian bees in one-frame observatory hive, purity of workers considered..... | 5 | 3 00 |
| Italian queen-bee..... | 5 | 3 00 |
| Honey-vinegar, one gallon..... | 2 | 1 00 |
| Apiarian supplies, best collection..... | 15 | 8 00 |
| Comb foundation for brood-chamber..... | 2 | 1 00 |
| Comb foundation for surplus honey..... | 2 | 1 00 |
| Honey-extractor..... | 3 | 2 00 |
| Wax-extractor..... | 3 | 2 00 |
| Bee-hive for comb honey..... | 3 | 2 00 |
| Bee-hive for extracted honey..... | 3 | 2 00 |
| Shipping-case for comb honey..... | 2 | 1 00 |
| Uncapping-knife..... | 1 | 50 |
| Smoker..... | 1 | 50 |

We trust that our Georgia subscribers, who can do so, will help to put up a good bee and honey exhibit. For any further information address T. H. Martin, Secretary, Prudential Building, Atlanta, Ga.

Honey=Muffins. Sift together one and a half pints of flour, two teaspoonfuls of baking powder, and a small half-teaspoonful of salt. Work in two tablespoonfuls of butter; add three beaten eggs, one cup of honey, and half a pint of milk. Beat thoroly and bake in a hot oven.—Good House-keeping.

EDITOR HUTCHINSON wants a good article on hunting wild bees. We don't know any one better fitted to write such an article than himself.

HON. J. M. HAMBAUGH, we learn, has recently been appointed inspector of apiaries for San Diego Co., Calif. Writing us May 18, he says:

"There has been a slight honey-flow from sage the past two weeks, but there will be little or no surplus. This is even more than was expected, owing to the long drouth. This section has been badly scourged the past two years."

PROF. A. J. COOK, of Los Angeles Co., Calif., writing us May 18, said:

"As I hoped would be true, the bees are getting quite a deal of honey. It may not last, but I hope it will."

We understand that Prof. Cook expects to come East in July. It is over five years since he went to California. We hope he will arrange to be at the Philadelphia convention, the first week in September. He would enjoy it, and so would everybody else.

THE SEVENTEEN PROMINENT CANADIANS, members of the "Senate of Canadian Bee-Keepers," shown on the first page, form a handsome group, and we are glad of the opportunity to present them to our readers. Mr. D. W. Heise, the "Noter and Picker" of the Canadian Bee Journal, referring to the group picture, had this to say in the same issue of the journal in which the engraving appeared:

"It is not often that I have occasion to find fault with my colleagues in convention, but when two honorable senators will so far lose their self-respect as did F. A. Gemmill and W. Atkinson, at Brantford recently, by making an aggravated assault on a photographer's personal property, in attempting to walk thru a supposed open door (a plate glass mirror) to interview the fellow whom they thought resembled themselves in the adjoining room, I consider it a lasting disgrace. The demand for immediate senate reform is justifiable, and imperative.

"While being arranged in a proper position for a snapshot in the picture gallery, where the probobates above referred to ran foul of the mirror, Mr. F. Holtermann (more commonly known as the editor of the Canadian Bee Journal) express a desire to be tickled down about the fourth rib; or that some one would tell a funny story that would cause the muscles of his face to contract and bring on a smile, which is very, very rarely found there. As this picker happened to be standing by his side, and owing to the disparity in our height, I was in a very advantageous position, and kindly consented to keep up the 'tickling' while the other fellows told stories (real funny ones). Now, dear reader, when that picture appears in the journal (which I expect will be with this issue, just observe the effect the tickling and stories had on that editor. Perhaps I 'tickled' too hard, or perhaps the other fellows told stories too hard. Instead of producing the smile, his countenance really takes on the expression of one in extreme agony, and no smile at all. Poor editor!

"This effect on the said editor reminds me of the Dutchman who purchast a small porker from his Irish neighbor. After keeping said porker until he grew big and fat, the pig-killing day arrived, and after breaking Mr. Grunter's skull with an axe, and giving him it in the neck' with a huge knife, of course Mr. G. lay motionless, and just as the Dutchman attempted to take him by the leg to place him in a more congenial position, Mr. Grunter decided to make his last kick on earth, with the result that his foot came with tremendous force against the Dutchman's 'bread-basket,' which paralyzed him for some minutes. When he fully recovered from the nervous shock, he exclaimed, 'Irish ish Irish, dead or alive!'

"Moral: A grim editor will be the same whether in a picture gallery or in his private sanctum."

Hildreth & Segelken, JOBBER AND COMMISSION MERCHANTS..... **HONEY, Beeswax, Maple Sugar and Syrup.**

120-122 W. Broadway,
 NEW YORK.

We desire to inform our friends and patrons that our firm has been re-organized and additional capital added. The business will be conducted under the firm name and style of

HILDRETH & SEGELKEN,

at the old stand, where we have had the pleasure of serving our friends for the past 11 years. Management and supervision will be the same and our business methods—those of square and honest dealings—will be practiced as heretofore.

We believe we have now the esteem and confidence of our shippers throuth the country, and that our dealings, as a rule, have been of the most pleasant nature.

Our additional capital will put us in position to increase our already large business still farther, if possible, and at the same time enable us to treat our shippers even more liberally than heretofore, in making advances, etc.

Records will show that we handle by far the bulk of all the honey sent to our market. We make honey the principal part of our business, are personally acquainted and have trade connections all over the country, which enable us to handle any amount of honey to better advantage than any other house.

Old shippers know us and will bear us out in what we have said. Those bee-keepers who do not know us and have had no dealings with us, we would cordially invite to correspond with us and make our acquaintance. We not only handle on commission but buy largely as well, from small lots to carloads, for spot cash.

We wish to call the attention of the Southern bee-keepers to the fact, that our market never was in better condition than this season. Old stock is disposed of and the market is bare, with a good demand. New crop will find ready sale and at higher prices than have ruled for years past. We would advise them to send their honey, while there is a good demand at good prices, as later on conditions of the market may change.

We also handle **MAPLE SUGAR AND SYRUP** very extensively, and would be pleased to hear from those having any of these goods to offer.

In conclusion, we wish to extend our thanks to all of our shippers for their past favors, and trust to receive their kind consideration in the future.

The "Golden Method" Compared With Others.

Query 00. What percent more of surplus honey do you think can be obtained by the Golden method than by ordinary methods?—OHIO.

- Jas. A. Stone—I never tried it.
- J. M. Hambaugh—I don't know.
- Dr. J. P. H. Brown—I do not know.
- Emerson T. Abbott—I do not know.
- Eugene Secor—I don't care to guess.
- S. T. Pettit—I don't think it a fair question.

A. F. Brown—My experience too limited to say.

Dr. C. C. Miller—I don't know. I never tried it.

Mrs J. M. Null—I have never tried the Golden method.

E. Whitcomb—I have never tried the Golden method.

P. H. Elwood—I have never tried the Golden method.

R. L. Taylor—None, I think, but I haven't tried that method.

W. G. Larrabee—I have no experience with the Golden method.

G. M. Doolittle—Ask Mr. Golden. Keep an "eye" on the reports regarding it, and compare them with others who use the

Queen-Clipping Device Free....

The **MONETTE** Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. ordinary methods. Time will prove more than my "think" possibly can.

Dr. A. B. Mason—I don't know; have not tried the Golden method.

O. O. Poppleton—I have no experience with the Golden method.

Mrs. L. Harrison—I have had no experience with the Golden method.

D. W. Heise—I have never tried the Golden method, therefore I cannot say.

E. S. Lovesy—With able, practical management I believe there would be very little difference.

Prof. A. J. Cook—Except one speak from experience, one better not speak. I have no experience.

Mrs. A. J. Barber—I have never tried it, and I do not believe it would succeed at all with us (in Colorado).

C. H. Dibbern—As I have not practiced that method I can only make a guess, and you can do that as well.

E. France—I don't know anything about the Golden method. All the method I know is "France's method"—get all you can.

Rev. M. Mahin—I have not tried the Golden method, nor seen it tried by any one else. I may not know as much about it as I think I do, but I have no faith in it.

J. E. Pond—I know nothing by practice of the "Golden method," and can say nothing of it by my own experience. As a matter of opinion, however, I am inclined to the belief that little if any gain can be made by its use.

C. Davenport—I have not tried this method, but I have great respect for what Mr. Golden says, or writes. He is a veteran, and belongs to that class who have done so much to advance bee-keeping from old-time methods to what it is at present.

Adrian Getaz—I have not tried the Golden method. Any kind of management that will successfully prevent swarming, or rather increase, will give far better results than the ordinary methods. In poor seasons it may make all the difference between some surplus and none at all.

G. W. Demaree—The answer to this question must be judged by the meaning the reader attaches to your expression, "by ordinary methods." In my experience as a honey-producer, more depends upon close attention to all present conditions—utilizing all the forces of the apiary at the right time—than depends upon the peculiar construction of the hive.

Colonies Very Strong.

I have been in the bee-business for the past four years, and I find a great deal of enjoyment in working with bees. I had 12 colonies last fall and I wintered them on the summer stands. I have been very fortunate as I lost but one. My colonies are very strong; they are Italians.
Whiteside Co., Ill. J. W. FISHERWOOD.

Northwestern Illinois Convention.

The bee-keepers of the western part of the Northwestern Illinois Bee Keepers' Association, held the spring meeting at the home of John Wagner, in this (Stephenson) County. The attendance was small, as the rain in the morning and the day before left traveling in bad shape, but those who were there seemed enthusiastic and hoped for better crops of honey this season. There was small loss reported, and bees generally in good condition.

Mr. Wagner met us at the station with his team and took us to his delightful residence where it was one's own fault if he did not enjoy himself, for Mr. Wagner and

Two Wagons at One Price.

It is a matter of great convenience and a saving of labor for a farmer to have a low, handy wagon. They save more than half the labor of loading in hauling manure, hay, grain, corn-fodder, wood, stones, etc. The man who already has a wagon may have one of these low, handy wagons at the small additional cost for a set of wheels. These Electric Steel Wheels, with either direct or stagger spokes, with broad-faced tire, are made to fit any axle. You can convert your old wagon to a low, handy wagon in a few moments' time. You thus virtually have two wagons at one price. Write to the Electric Wheel Co., box 16, Quincy, Ill., for their catalog, which fully explains about these and their Electric Handy Wagons, Electric Feed Cookers, etc.

wife had everything in good style, while they had provided enough for a full-sized camp-meeting. I hope they may live many years and have their share of honey.

We mist many faces that we have met at our conventions, and saw some new ones which we hope to see at future meetings.

JONATHAN STEWART, Stephenson Co., Ill., May 15.

Moving Bees to an Orchard.

The loss of bees here the past winter has been heavy, especially among farmers, at least 75 percent. I lost 5 out of 46 colonies. The weather for the past month has been very favorable, and they are breeding up fast. The prospect for clover and linden is good.

A man living 1 1/2 miles from me came yesterday to get me to put 20 colonies or more in his 80-acre apple-orchard for 10 days, to fertilize the bloom. He offered 15 cents a colony. I took 10 colonies, but do not like to risk moving many now while they are gaining so fast here. Wayne Co., Iowa, May 11. J. C. DAVIS.

Very Dry Weather.

The weather here is very dry and bees have done nothing up to date. As is usually the case, as soon as the trees blossomed cloudy weather set in. There will be no clover honey unless rain soon comes along. HENRY ALLEY, Essex Co., Mass., May 19.

Heavy Winter Losses.

Nearly all the bees wintered out-of-doors were lost. One bee-keeper has only 15 left out of 56 colonies; another has one left out of 26. Those who cellared their bees are much better off—loss very light.

The weather now is very unfavorable for the bees—cold and rainy nearly all of the spring—in fact, very few good days for them. From all accounts the "golden's" have wintered best. GEO. RANDALL, Cherokee Co., Iowa, May 20.

One of the Hustling Brownies.

I have three honey flows here and it doesn't seem likely that all of them will fail. I am trying hard to get my dishes right side up to catch all the flows. I do believe I am in a good location for bees. I have just extracted over a barrel of honey that was in the way of the queens. (You see I put them into winter quarters with a plenty.) I have put extracting supers on some of the strong colonies so they can remove the honey from the brood-nests and make room for the queens, and the bees are rushing the honey up-stairs just as I told them to. They have been getting considerable from fruit-bloom. What they are working on just now I do not know, but they are getting their "daily bread."

I am almost as busy as the blessed bees are; I get up every morning at 4 o'clock, and I work at not a thing but bee-keeping. Erie Co., N. Y., May 23. E. W. BROWN.

King-Birds Destroying Bees.

I had a little experience to-day that was quite unusual in fact I never heard any thing like it in bee-experience. It has been cold, cloudy and windy for three or four days, finally ending in a cold, driving rain, and I suppose the birds have become very hungry. To-day the bee-birds gathered in my apiary to the number of two or three dozen, sometimes two or three sitting on one hive. It was cold and windy so there were but few bees flying, otherwise I believe they would have done considerable damage. I tell you, seeing is believing, and it will be useless to try to convince me that the king-bird is anything but an enemy to the bee-keeper. Why, they would actually sit on the corner of a hive and watch down at the entrance, and if a bee showed her-self or took wing she was gobbled up in short order. The past severe winter seems to have

BEE-SUPPLIES, Root's Goods at Root's Prices. Langstroth Hives and everything pertaining to same. Muth Jars, Muth Honey Extractor—in fact everything used by bee-keepers. Send for our Catalog. C. H. W. WEBER, 2146 Central Ave., CINCINNATI, OHIO, Successor to CHAS. F. MUTH & SON and A. MUTH. Honey and Beeswax Wanted. 15Att Please mention the Bee Journal.

CHAS. F. MUTH & SON.

I wish to announce to my friends and patrons that I have this day sold to C. H. W. WEBER, of Cincinnati, my Honey and Bee-keepers' Supply business, known for the past 38 years as CHAS. F. MUTH & SON. Mr. Weber will continue to push the Langstroth hive and everything pertaining to same; besides, he has secured the agency for Mr. Root's goods, and will sell them at his prices. I beg the customers of the old house, to whom I wish to extend my thanks, to continue their patronage with Mr. Weber, by whom I am sure they will be accorded fair and honest treatment.

MRS. ANNIE MUTH Widow, Cincinnati, Ohio, April 7, 1899. 15Att

made away with all kinds of insects, so I suppose the birds are hard prest for food.

Bees that were left out-doors last winter almost all died. I heard of one man who had 18, lost all; another who had 12 or 14, has one left; another, who had a big dry-goods box that has had a colony in it for four or five years, always wintered on summer stands without protection, is now out of the business. My own loss is about 10 per cent, mostly all owing to leaving out doors, my cave being too small to hold all.

The bees have done fairly well up to the present, but fruit-bloom is a failure on account of cold winds and rain, so I suppose we will have to feed some.

All my alsike clover winter killed, but there is some white clover left, and perhaps the present wet weather may bring it on in good "shape" yet. **E. S. MILES.**
Crawford Co., Iowa, May 14.

Preserving Fruit with Honey.

On page 221 is an item in regard to preserving fruit with honey instead of sugar. Some years since I carried on business in St. Louis, and among my stock I kept fruit and honey. A customer of mine wisht me to be sure to secure her a couple of bushels of damson plums, and as they were very scarce in that vicinity, I had to send to Indiana for them, and obtained about four bushels; by the time I got them and paid the charges and first cost they stood me a pretty good figure, and then my customer backt out, and I was out—both pocket and temper.

I kept the plums a few days, and could not sell them. I had in the shop about 500 pounds of extracted clover honey, very fine, and I decided either to spoil a whole lot of honey and all the plums, or else make my money out of them.

I treated the plums the same as I would to preserve them with sugar, but instead of pound for pound I used two pounds of honey to one of plums. I put them up in gallon stone jars, covered them with paper,

300 Cases of Second-Hand 60-pound Cans

We have found another lot of 300 cases (two cans in a case) of second-hand 60-pound Cans practically as good as new. We offer them at 45 cents per case in lots of five, f.o.b. Chicago; or in lots of 10 cases or over, 40 cents per case. Address,

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

and then tied a cloth over them, and set them in the back end of my ice-box. At the end of a month I sampled them, and one taste was enough. They were bitter, pungent, and tasted bad generally. I left them in the ice-box until November, and then took them out and set them in a cool place until Christmas, when I sampled them again, and found they had undergone a complete change for the better. I only had to offer them for sale, and got \$2.00 per gallon for them, and calls for more.

I think that using double the amount of honey with many of our fruits will prove very successful.

J. H. HERMANE,

Garland Co., Ark.

Thirteen-Year-Old Josie.

On page 292, Cogitator asks if that 13-year-old Josie is a boy Josie or a girl Josie. Well it *was* a 13-year-old girl Josie, but now I am 14 years old, and I think I ought to eat more honey than before.

MISS JOSIE M. TICHENOR.

Crawford Co., Wis.

Several Apiarian Paragraphs.

Years ago a bee-keeping friend went to one of the most successful apiarists we have here, to find out how to prepare his bees for winter, and the satisfaction he got was that he would have to learn it. The questioner had been losing his bees quite heavily during winters, and wanted a remedy for the evil. Here is the remedy as I have found it:

Buy a text-book, subscribe for one or more bee-papers, and thus get valuable information from those who let their light shine.

Do bees ever carry eggs from one cell or comb and place it in another? For myself, I believe it is such a delicate piece of work that bees have never done it.

Honey-dew was gathered quite plentifully in 1898, judging from the amount found on the market last December. It is a pity, for it burts the sale of honey from fall flowers, such as touch-me-not, which is our main source here.

The honey-dew I found on the market was of a somewhat dark color or reddish cast, and did not granulate, while fine honey from fall flowers granulated as soon as cool weather came. The amount of damage done by honey-dew is hard to estimate, as the market was well supplied with the vile stuff put up in glass tumblers with the producer's name on it. I should think that one glass of such honey would satisfy one's appetite for a long time. I am disgusted with that kind of business.

We have a basswood shade tree that comes in bloom a week later than other trees here, and goes out of bloom about a week later than other basswoods. It has bloomed this way for years—ever since it began to bloom.

C. A. BUNCH.

Marshall Co., Ind.

About Wintering Bees, Etc.

In reading Miss Fannie C. Damon's failure in wintering her bees, I thought perhaps the way I had mine protected at the entrance might be of use to her, or some one else that did not do the same way.

I did not know how the winter might be, so at the commencement of the snow, I had a lot of bottom-boards made. I set one on its side at the entrance of each hive, a little way out at the bottom, then leaned it close against the hive at the top, so that it made a space under it. When it snowed I would get thru the snow to each hive, and draw the top out enough to get the snow from the entrance and put the board back. I would leave it banked on the north side to keep the cold out, but clear it away on the south side, so no ice formed at the entrance. I had Hill's device on each brood-frame, then canvas over that, the top on, and a cushion on that. Some of the cushions had cork, and some dry grass in them; that was all the protection they had except what I told in my previous letter. I don't see any difference between the ones I used

the fodder around and the ones I had the boxes around. All did well.

I have changed four of my hives to the Golden method. I intend to put the first swarm into them and see whether I can do any better with them than with the others. If I do, so much for having the American Bee Journal, which I could not think of being without, nor should any one that has any bees. I am anxious to see it every week; if I get my mail on Friday it is always on hand.

We have had a cold, late spring. I hope we will have better weather soon. We have had a cold, late spring ever since I have been in the bee-business—three years.

I see a question about putting bees into the garret. A friend of mind has three colonies in his garret, and they have done well. I think he took the frames out of the hive and put them in a box. I did not see the box, but it was long enough to put one hive in each end, a space between each one, and a hole made in the weather-boarding opposite each one, and fixt so they could not get out into the house. The box has a tight cover to it, so they can look in by lifting the cover. He told me they had stored handsome honey. They are on the south side of the attic. He said they all used the same passage-way now, that is, the two in the same box. I believe he said he took a piece of tube and put in the box, and cut thru the siding, and made a little alighting-board outside, as it bothered them to strike the hole right.

Mrs. SARAH GRIFFITH.

The Novelty Pocket-Knife

A heavier and strouger knife than the one we offered heretofore.)

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the Subscriber.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the Novelty is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the Novelties, your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be apprised of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$5.00), and we will also send to each new name a copy of the Premium Edition of the book, BEES AND HONEY. We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, May 8.—Not anything of consequence doing; a little honey is being sold at prices that have been prevailing for some time. White comb is scarce, but there is a surplus of dark. Extracted unchanged. Stocks light. Beeswax, 27c. R. A. BURNETT & Co.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10c; dark and amber, 8c. Extracted in fair demand without change in price. Beeswax, 25c to 26c.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey. M. H. HUNT.

NEW YORK, May 9.—Fancy, 7c; choice, 6c; fair, 5c; common, 5c per gallon. Beeswax quiet at from 20c to 28c, according to quality.

Our market is in first-class condition, being bare of extracted honey, and demand good. New crop is beginning to arrive from the South. Comb honey is well cleaned up; some demand for white but demand for dark has ceased. HILDRETH & SEGELKEN.

SAN FRANCISCO, May 3.—White comb, 10c; 10c; amber, 7c; 9c. Extracted, white, 7c; 7c; light amber, 6c; 7c. Beeswax, 20c; 27c.

In quotable values there are no changes to record. A ship clearing this week for Siberia took 231 small cases of extracted, being honey repack by jobbers. There will be a fair yield this season in the San Joaquin, probably 150 cars, mostly alfalfa honey, but the production will be very light in the balance of the State.

BOSTON, May 17.—Fancy white, 12c; 13c; A No. 1, 11c; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7c; 8c; light amber, 6c; 7c. Beeswax, 27c; 28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded, some, too, as stocks are a little heavier than is liked at this season of the year. BLAKE, SCOTT & LEE.

KANSAS CITY, May 15.—No. 1 white comb, 15c; fancy amber, 14c; No. 1 amber, 13c; fancy dark, 13c; No. 1 dark, 12c. White extracted, 6c; amber, 5c; dark, 4c; 4c. Beeswax, 25c. C. C. CLEMONS & Co.

CLEVELAND, March 9.—Fancy white, 13c; 14c; No. 1 white, 12c; 13c; A No. 1 amber, 10c; 11c; No. 2 amber, 9c; 10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11c; 12c; some very poor selling at 6c; 7c, and dull. No more business in honey before the opening of the ensuing season. BATTERSON & Co.

OMAHA, May 18.—It is a hard matter just now to give quotations that would have any meaning at all. With the exception of small lots of buckwheat—very good for its kind, but it is not the kind wanted here, which dragged at 8c; 9c cents there have been no new receipts, and there will not be a pound of honey carried over in dealers' hands. First receipts of new crop will certainly be pickt up eagerly at fancy figures. PEYCKE BROS.

CONTRIBUTED ARTICLES

The Once Famous Linswik Sisters and Their Experience with Bees.

BY EDWIN BEVINS.

SOME time ago Editor Hutchinson visited the Linswik sisters at their home in northern Michigan. I am indebted to one of these sisters—the one with the beautiful name—for the method I use in rendering beeswax, and

also for some hints on the wintering of bees, which hints I found in a stray number of the Review received long ago. I read the story of the sisters' experience in bee-keeping with considerable interest, also with some surprise and some pleasure. Surprise that their interest in the pursuit has dwindled to the keeping of only five colonies; pleasure at knowing that they keep these, and have kept more, partly because of the things connected with the pursuit which they would not sell for cash if they could.

I am sorry to learn that the sisters are now suffering the penalty for too much early zeal, that a reaction has come, and that weariness has followed endeavor. At the age when I commenced the keeping of bees enthusiasm is dead or dying. A person at that age, if he has been at all observant, has seen too much of life and the world to be any longer the victim of illusions. Whatever is undertaken is apt to be undertaken with more or less of deliberateness and calculation. And yet, I sometimes wish the old boyish

The Old Home of Two Lady Pioneer Bee-Keepers in Michigan From the Bee-Keepers' Review.

enthusiasm would come again. As that cannot be, I mean to husband the resources of muscle and mind so that I may always feel a *little* like a boy, even if I live to be a hundred years old.

Other bee-keepers besides the sisters have tried so hard to know everything and do everything pertaining to the pursuit, till nerve and brain have become so weary that they turn for rest to something else. There are many things pertaining to apiculture which the honey-producer can afford not to know. It is no great matter to me whether a swarm of bees is an organ or an organism. It is of considerable importance to me to have every colony in the yard in the best possible condition to do efficient work when the time for work comes round, and my efforts will be directed to this end.

One mistake of the sisters—repeated by many no doubt in these later and better days—was in reading so little before they undertook to do so much. The bee-papers (any of them are great helps to the beginner, and he should study the advertisements with special care. They will save him many a dollar. Then there are hints to be found all thru their pages that will save the young bee-keeper from making many mistakes. In order to get the greatest good from these hints it is necessary for the beginner in bee-keeping to get and study a good bee-book till he has become tolerably familiar with bottom facts and first principles. Then the beginner will not have to ask a whole lot of foolish questions—questions that, later in life, he will be ashamed that he ever asked. And then Dr. Miller will have a little rest, as his occupation will be partly gone.

The Linswik sisters, it seems, have found out that there is not a great deal of money to be made in honey-production. Some others, it seems, found out the same thing years ago, and degenerated into book-makers and supply-makers for the throngs of new and old bee-keepers who have hopes of succeeding in a pursuit in which the others had found large success impossible.

I am not building any castles in Spain or here, out of the proceeds of the apiary, but I have kept bees long enough to feel assured that there is reasonable pay for their intelligent and economical management.

Decatur Co., Iowa.

[Cyula Linswik and her sister (altho that's not the real name), as Mr. Bevins says, kept bees in northern Michigan, and the older readers may remember how delightfully were told in the bee-papers their haps and mishaps. All that was years ago, and nothing has been heard from them for a long time. Very pleasant it was, on opening the Bee-Keepers' Review for November, 1898, to find an elegant picture of the old home of the two ladies, and also their present home, together with a sketch of their career written by the same pen that so charmed us years ago. (Thru the kindness of the Review we are enabled to show the same pictures to our readers).

In 1869 they took up their abode in the old home, a log house surrounded by "the forest primeval," with bears, wolves and deer for neighbors, the nearest post-office being reached by a trip of 20 miles over an unspeakably bad road.

Minute particulars as to the result of their bee-keeping are not given, but Editor Hutchinson avers that they have been very successful, he, himself, from first to last, having paid them several hundred dollars for bees, and he says the honey they produce is as fine as any he has seen. The little that is told as to their bee-keeping career, as written by one of the sisters, is here given in full: [EDITOR.]

In December, 1871, there appeared in the New York Tribune an interesting report of the meeting of the American Bee-Keepers' Association, at Cleveland, Ohio. Glancing it over, my attention was arrested by the fact that two ladies took a prominent part in the proceedings; and that they recommended bee-keeping as pleasant and profitable employment for women. Correspondence with these ladies

ensued, advice was asked, received and acted upon with this result: Early in May, 1872, I became the happy possessor of a colony of Italian bees, which had cost me only \$25.00, plus nearly \$5.00 express charges! When, in June, my sister came home from a six months' visit with a brother in the South, she became my efficient helper and full partner in the enterprise.

We began with no knowledge whatever of bee-keeping; nor had we a bee-keeping friend or acquaintance. The Italian Bee Co. Mrs. E. S. Tupper and Mrs. Annie Savery—of whom our bees were purchased, had recommended to us a small text-book and a monthly bee-journal partly devoted to agriculture. As the publishers of this journal did not advertise rival publications, nor give the address of correspondents, we were shut out from access to the bee-keeping fraternity. Still, much of our text-book's teaching was good, and often the paper contained interesting and valuable articles from the pens of writers of repute. Perhaps it was as well that, for our first year, we were not too much distracted by opposing counsels, even at the price of some mistakes.

Early in the year 1873, at his office in Saginaw, I met the late Dr. J. C. Whiting, and learned, from some chance word, that to the duties of his profession he added the pleasures of bee-keeping. During the remainder of that sitting every opportunity for articulate speech on my part was filled by a question. I think Dr. Whiting recognized it, compassionately, as a case of bee-fever in the acute stage;

Present Home of Cyula Linswik and Her Sister.

for, in addition to the kindly patience with which he answered all my queries, he quite overwhelmed me with gratitude by offering to loan me a bound volume of the American Bee Journal. It was, I think, the first volume after the interruption in publication made during the war. As I turned its pages at home, I could scarcely believe in my good fortune—that a stranger from the remote backwoods should have been trusted with such a treasure! It was our *open sesame* into the bee-keeping world.

We soon had in our possession the works of Langstroth and Quinby, while the American Bee Journal, the Bee-Keepers' Magazine and Gleanings—we began with the first tiny copy of the latter—were regular visitants.

And thenceforth how we studied and experimented, and rejoiced over our bees. Ah, me! that such enjoyment cannot last. That the enthusiasm must die out, leaving only a faint thrill at the memory thereof—the memory of those early days when the bee-yard was a charmed spot, a refuge from loneliness, despondency, even one's own bad temper! And later, when we had more work than play in the apiary, it was still enchanted ground—a place where one could forget the dinner-hour (if there chanced to be a maid in the kitchen), forget the temperature (with the mercury in the 90's), and be totally unmindful and unconscious of extreme weariness—until nightfall and a summons to the supper-table made it only too apparent.

It would have been *pleasant* employment to the last,

had health and strength remained equal to its demands; but there came a time when we thought best to recognize the need of almost total abstinence from the bee-yard. For several years we have aimed to begin the season with no more than two or three colonies, and give to these the least attention possible, without a murmur to let swarms escape and go to the woods, and to cheerfully put off till to-morrow, or next week, or next month, even, the removal of sections which should come off to-day.

Did we find our bee-keeping profitable employment? That depends; if you mean something more than modest wages for time and labor spent—no! But if we may count as gains returns which cannot be measured in dollars and cents—yes!

Nov. 3, 1898.

CYULA LINSWIK.

"Getting Farmers to Keep Bees."

BY WM. M. WHITNEY.

UNDER the head of "Editorial Comments," page 264, we find the following quotation, viz.:

"What shall it profit a man if he gain the whole world and lose his own soul?" This is, in my opinion, just what we as bee-keepers are doing when we try to keep our farmer brethren out of the bee-business. Let me give you some reasons why it will pay us to induce our farmer neighbors to keep a few bees:

1st. Farmers are learning that they must spray their fruit-trees, and in so doing are slaughtering bees by the wholesale. Now, if every other farmer owned one colony each, just a hint to them that they might kill all of their bees would be sufficient to prevent this evil.

2nd. It would be no trouble to get them to subscribe for our modern bee-literature, and thus learn that it requires some effort on our part to produce a paying crop of first-class honey. And they would appreciate our efforts to produce good honey. No teacher is as good as experience.

3rd. They would learn to like honey, and so would consume more of it, thus advancing the price of a first-class article.

4th. The final outcome will be I speak somewhat from experience, not more than one out of ten will ever make a success of bee-keeping, thus no more honey produced, but each one, having acquired a taste for honey, will never again be found without honey on his table, thus much more consumed. And they will all say, "I see now that you people earn your money, and that dollars don't roll uphill to you without effort on your part, as I once believed they did."

Now, I honestly think that this is a fair probability of results; and having cleared my conscience of what seemed to me a duty, I submit the foregoing.

J. H. TICHENOS.

Now, Mr. Editor, if you had not taken the above advice somewhat seriously, it would seem scarcely to merit a notice. Under the circumstances, I can hardly refrain from telling you what I think about it.

Why the author of the above reasons (?), for the encouragement of farmers to go into the bee-business, should have made choice of the text which he did, from which to preach a sermon, such as he has attempted to do, passes my comprehension. He tells us in his introductory (before he reaches *Firstly*), that we are in danger of losing our own souls by trying to keep our friends and neighbors out of a business which, in his *Fourthly*, he admits that nine out of ten of them would make a complete failure in attempting. Now, it seems to me, that if we take the advice of our "preacher," and encourage our neighbors to do that which we know they stand ten chances to one to make a complete failure in, we are not doing by them as we would have them do by us; and all for the sake, as the sequel shows, of putting a few paltry dollars into our pockets; or, in the language of the text, "to gain the whole world."

The whole proposition seems to be obscure. The "preacher" denounces us for that which he says we are doing, and which we have been taught to believe was according to the spirit of the Gospel, and advises us to do that which it seems his text plainly condemns.

One is reminded of the sermon of the colored preacher in the South, during the days of slavery. He told his hearers that if they did evil, and served the Devil, they would be sure to get "Demnition;" but if they loved the Lord, and served Him, they would receive "Condemnition." One brother, who seemed to grasp the situation, shouted, "Den dis darkey'll take to de woods!" Now, I must confess that in the light of the instruction here given, I'm inclined, like the darkey, to "take to the woods." The only safe course for bee-keepers to pursue, under the circumstances, is to say nothing to their neighbor upon the subject, neither pro nor con, for if they do they will get "Demnition" anyhow.

But, seriously, let us consider some of the ideas here advanced. Suppose that every other farmer were induced to keep at least one colony of bees, and, by appealing to his selfish interest, he were kept from spraying his fruit-trees while they were in blossom, what good would that do if the other half of the farmers who don't keep bees saw fit to

continue spraying? You see, that to make a success of the scheme the whole fraternity must be brought in.

Well, let us bring a little arithmetic to bear upon the question, and see what the result will be. There are (as an estimate), in round numbers, 300,000 farmers in the State of Illinois; and if each were to commence bee-keeping, it would require an outlay of at least \$10.00 to begin with, making a total outlay of \$3,000,000 for the entire State, nine-tenths of which—or \$3,240,000—is to be absolutely squandered for the sole purpose of instructing the farmer in the matter of spraying his fruit-trees, and to create a taste for honey. Indeed, experience is a faithful teacher, but the price this time is pretty high.

It is not overstating the case to say that at least nine out of every ten would make a complete failure of the business, and the greater number would get no honey with which to create a taste for more. And, again, not one in a hundred would think of subscribing for a bee-paper; in fact, but few take even an agricultural paper.

I would like to draw a pen picture of what would follow such a scheme in about three years after its inauguration, but time and space will not permit. No, no, it will not work; and if the author states the facts of the case it ought not to. "For what shall it profit a man if he gain the whole world and lose his own soul?"

Kankakee Co., Ill.

A Half-Dozen Questions Answered.

BY G. M. DOOLITTLE.

I AM requested to reply thru the American Bee Journal to the following questions, which I will do with the editor's permission:

GETTING BEES TO BUILD COMB.

QUES. 1.—"Is there any way to get bees to build comb when they are disinclined to do so? I fed some colonies until all the vacant comb was filled, but they would not draw out the foundation. This has reference to brood-combs exclusively."

ANS.—I do not see why you failed here, unless your foundation had some other material in it besides pure bees-wax; for in all of my experience in feeding, the bees would work foundation as soon as they began to secrete wax to lengthen out the cells or cap over the food. But had the bees been persistent in using the combs in the hive rather than work out the foundation, you could have made them work it by taking their combs away from them and allowing nothing but foundation. In this case they would have to work the foundation in order to find space, or a place to store the food, after they had their honey-sacs well filled.

INDUCING BEES TO WORK OVER WAX.

QUES. 2.—"To what extent can bees be induced to work over wax? Do you not suppose wax could be incorporated with thick sugar syrup in some way so that the bees would work it the second time?"

ANS.—There has been considerable experimenting along the line of having old wax worked over by the bees, such as shaving it up in syrup, etc., but I believe it has been acknowledged by all who have tried it, to be a waste of time and wax, when compared with having the wax made into foundation.

STRAIGHTENING BUCKLED OR BENT COMBS.

QUES. 3.—"What is the best course to pursue with brood-combs that are buckled or bent, so that some of the cells are not deep enough for breeding? Is there any way of bringing them straight? The foundation evidently became bent before the bees worked it out."

ANS.—There was a neglect on the part of some one in having the foundation bent when it was given the bees, or in giving it at such times that the bees did not commence work on it at once, before it had a chance to warp or twist about in the hive. It is best to give brood-foundation to bees only at such times as they are wanting more combs; for unless they do so want, it will not be touched by the bees unless perchance to mutilate it, because they have nothing to do but mischief.

Then, it is generally better to use foundation in the brood-chamber only in connection with wired frames, which entirely prevents the foundation from sagging or twisting about. But having combs as described, there are two ways of fixing them fit for use by the bees. The first is, by melting them up and working over into foundation again—a plan recommended by some of our more advanced bee-keep-

ers, but a wasteful plan, as I consider it, unless the combs are too crooked; and, secondly, straightening them in the spring of the year when pretty much free from brood and honey. Take them from the hive to a warm room—whose temperature is up to 90 or 100 degrees—and, when thus warm and pliable, lay on a flat surface and press them in conformity to that surface, cutting out a little strip of comb if necessary, where the worst bulged, so that the combs will come straight without spoiling too many cells by pressing them out of shape. Years ago I straightened many combs in this way, before foundation was known, so that the combs in all of my hives were as straight as a board, and many of these straightened combs are still in my apiary.

DIFFERENCE BETWEEN BEESWAX AND PROPOLIS.

QUES. 4.—“What is the difference, chemically, between beeswax and propolis? Is propolis a special product of the bee as wax is? Do bees consume anything to produce propolis?”

ANS.—Beeswax is a fatty substance peculiar to the bee, and produced by the consumption of honey on a plan similar to animals, such as the hog and cow consuming grains of various kinds to produce lard and tallow, the same being of a fatty nature, but differing from beeswax to a considerable extent. Who can tell us more on this subject, as I am no chemist?

Regarding propolis, bees do not produce it at all, but simply gather it from the resinous exudations of certain plants or trees, and from old hives, etc., where it has been previously placed by other bees. The tree known as the balm-of-gilead, and the horse-chestnut, give the most of the propolis gathered in this locality, the buds being well covered with this resin during the greater part of the summer season.

DO BEES KNOW BEST AS TO UPWARD VENTILATION?

QUES. 5.—“Do you believe the bees know what is better or best for their good? If it is best for them to have upward ventilation, do you not suppose they would provide therefor instead of sealing everything up tight at the top of the hives?”

ANS.—I have my doubts whether bees know what they want along this line, but accept the surroundings as they find them. It is their nature to seal up all cracks and holes not large enough for their exit or return, and this they will do, no matter whether in a tree or hive; but after seeing them prosperous in trees which had only a hole large or small at the bottom of their combs, and all the way from this to a crack large enough to put your hand in the whole length their combs occupied in the tree, I have concluded that they accepted things as they found them, as said above, without asking whether such were the best for them or not.

THE “BALLING” OF QUEENS.

QUES. 6.—“What is your remedy where bees ball a queen? Why do bees ball a queen of their own rearing, after all queen-cells have been destroyed, and they can have no hope of any other queen?”

ANS.—The last part of this is a mystery which I never could really solve. It is easy to say that, in opening hives, the bees fear that their queen is to be injured, so ball her for safe keeping; but I have known scores of instances where a virgin queen has been balled in coming home after meeting the drone, and at other times until they were killed, or nearly spoilt for future use, being led to the discovery that the queen was being balled by the general appearance of the colony at the entrance, such as an unusual commotion denoting queenlessness, or dead and doubled-up bees, having the appearance of being stung. Who can tell us why such balling occurs?

The remedy is the same as in introducing queens—that of caging them until the bees behave themselves, and are peaceably inclined toward them. Smoke the bees till they release the queen, then cage her and leave her till the bees pay no more attention to the cage than they do to any other part of the hive. When you find this to be the case, it is generally safe to let any queen out.

Onondaga Co., N. Y.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

The “Old Reliable” seen through New and Unreliable Glasses.
By “COGITATOR.”

MOths AND ROBbing.

“The only good bee-keeper is a dead one!” quoth Harry Howe, page 258. Come to think of it, it was not verbatim that he thus chucked us into the proverb relative to the poor Indian but it amounts to that, if neither robbing nor moths ever trouble the G. B.-K. Let’s compromise, dear Harry, and put it that the evils of moth and robber are greatly mitigated by wise forethought, and by always being on hand in time.

A NEW WRINKLE—ROBBERS ROBbing THEMSELVES.

Few things take better in a journal than new wrinkles; and I think that we must credit Mr. Howe with quite a wrinkle in that he combats robbing (must be a shockingly bad bee-keeper) by keeping the robbers constantly employed at robbing out their own honey; heavy combs being continually taken out and carried to the robbing spot. Of course, this would not be practical where there are outside bees handy; but where it is practical it seems to combine an excellent sort of stimulative feeding with a clever device to keep rogues out of mischief. All the same, let’s wait for our individual afterthoughts after we’ve tried it. He’s right, that what honey we desire to feed thus *can* be exposed (discreetly), and no serious harm follow. It is a wise point that we should, if possible, avoid letting them realize that we have shut them out from plunder, or carried it off.

SAFE INTRODUCTION OF QUEENS.

Frank Coverdale’s safe introduction is worth thinking of. A queen once O. K. in a nucleus, the nucleus can soon be made to absorb the most of any designated full colony. But it’s tough on the queen just arrived from a long journey to make her wait two days more on the shelf; and mails and dealers are seldom regular enough to have things match exactly. Page 258.

THE CLUSTER OF BEES IN WINTER.

Out of W. G. Larrabee’s excellent paper at the Vermont convention I call the remark about the danger of getting the winter cluster established on nearly empty upper frames, while most of the honey is left in the lower frames—quite out of cold weather reach. Queens below, as much as may be, should be the rule. Page 261.

NIGHTBEE VS. THE NIGHTMARE.

It seems (page 262) that Mr. Holmes, who sleeps in his house-apiry occasionally, has at times experimented with the *nightbee* (sharp end first) as an improvement upon the nightmare. (No danger that money would make it go.)

QUEENLESS COLONIES IN HOUSE-APIARY.

It was shrewd to move in the weak colonies last, after getting them strengthened up with the obstinate bees that prefer an alien home near by to own home a little further off. I have seen bees in process of being moved show that same trait, even when moved only a few feet at a time. But 16 out of 29 is a sad proportion to go queenless in summer when young queens come on deck. We’ll be excused from house-apiaries, if that ratio is to be the rule. Page 262.

DR. MILLER AND HIS “Q. AND A.” DEPARTMENT.

And so Dr. Miller has encountered a man who thinks that the questions in the department of “Questions and Answers” are made up! Mist him that time. Accuse him of making up the answers, and see what he’ll say then. When Mary told her dream her mistress smilingly accused her of being asleep when she dreamed it which she indignantly denied.

BARRELS FOR HONEY A GRAND NUISANCE.

Right, you are, dear editor, about the barrel. The dealer who buys it and sells it again whole thinks it O. K., naturally; but to the retailer it is a grand nuisance. Quite a good few of us don’t admire the job of taking the head

out of a barrel—and perchance *couldn't* put it in again properly—yet it is too costly a package to waste. Page 265.

BEES AND SORGHUM-MILLS.

Mr. Pierson's experience, on page 268, is pathetic. Still I think that on a pinch one *can* have an apiary and make sorghum too. Don't *plug* the entrances. A little labor and expense betimes will make each colony a nice front apartment of screen. Many years ago I ran a sorghum-mill one fall. We kept bees then, did not shut them up, took few other precautions, almost none, and had very little trouble. Orion Conger, page 283, finds bees unendurable only one year out of eight. Some other years he fought them off a little with smoke.

DANDELION TEA AN ENDURABLE INSULT.

Alas, alas! Our Dr. Peiro (progressive as he has seemed to us to be) is non-progressive enough to believe in some of the old gags. Insulting one's stomach regularly with dandelion tea actually does people good. Page 270.

NO LIKEE STINGEE SUGAR-FLY.

As I contemplate that poet yelling about a few stings, on page 281, it occurs to me to ask a question. Do we ever get sufficiently habituated to stings to *like* them? Some stings I decidedly don't like, including all the extra-severe ones; but still, I often find myself asking of myself, Does that hurt? or, Does it feel good? How is it with the other old chaps? Are any of them similarly affected? Better spring medicine than Dr. Peiro's dandelion tea, I believe.

NAILED SECTIONS AND A PORTLY DAME.

On page 275, Boomhower's charge on Doolittle for saying that the ordinary section breaks down, seems to indent his lines somewhat. When a case can fall ten feet, and smash the honey all up, without harming a section, it does seem as tho' fair quality must be accorded to the latter. But it seems that that 200-pound, red-headed dame pushed back his own lines a few paces; and yet, with the help of the bees, he won out. Perhaps Doolittle may do as well; still retain a sort of hopeless hankering after the nailed section myself, you see.

PROTEST AGAINST HONEY WASHING OUT.

In Lovesy's excellent article, page 273, I would file a protest where he says rain washes the honey out of alfalfa. If I am right, there is none to wash out—scarce a bee ever seen on it in any weather wet or dry, thru an extensive territory—and yet abundant honey-yield in the irrigated regions. It seems to be a sort of general rule that plants do not yield much honey except in regions where they specially prosper. Plants made to grow out of their natural habitat very rarely prove honey-producers.

DARK AND LIGHT HONEY-DEW.

Mr. Whitney's interesting problem about one colony gathering only dark honey-dew, and another only light, I would essay to solve thus: The dark supply began first, and those colonies that got to work on it strong kept at it. In some other colonies the main generation of bees were not old enough to gather till several days later, and they struck into the later and better supply. Of course, *bees* don't consider honey any the worse for being dark; and their taste for flavors probably differs some from ours.

FORMULA OF BEES' BABY FOOD.

And so, Honey 2, Pollen 4, Water 1, is the recipe the bees follow for baby food, according to Doolittle's after-think. Page 276.

A TRIMMING FOR TRIMBERGER.

"The loquacious paid writer," eh? Why, Mr. Trimmer, no judge will ever let you off from the charge of being loquacious, the way you sling English. But I guess you're right, that watery-looking honey is usually honey left uncared for in hot weather by the swarming of the bees. Not quite so sure that a hot, dry room will reclaim such honey; but perhaps it may sometimes. Certainly the acid will not counter-develop if souring has begun. Rather doubtful if cappings which have sunk to touch the honey can ever be made to leave an air-space. I was going to scold about those half-capt sections given to the minister; but I forbear. My last run of unfixed sections are apt to be dark and poor and raw; but where there is no fall harvest they may be much better—possibly as good as the minister's sermons. It is instructive to see a competent judge abandon the Taylor leveler for a better method. If it seals over

empty cells, and they appear as blemishes in next year's honey, that is a drawback, indeed. Why has no one mentioned that before? On the whole, a convention seldom listens to so stir-up-ative a racket. Page 277.

PLANS TO HEAD OFF SWARMING.

Cutting out and throwing away the brood to head off swarming is remedial work with a vengeance, Mr. Lathrop and job lots of it, if we examine each colony often enough to know just when to cut. And your nice frames of worker-comb will be changed to drone.

The other plan will bear more investigation. Had Mr. L. told us how many colonies, up to date, actually *have* been run in this manner it would have helped on some. Page 278.

ALBINO BEES POLLEN SUBSTITUTES.

Probably the albino bee is not a true albino, and so inferences of weak constitution founded on the name would be amiss. Page 285.

I conjecture that Mr. Presswood's flour and meal may be all right, only that the bees are waiting for a trifle of nectar, and more springlike weather. Page 285.

COGITATOR.

Report of the Chicago Bee-Keepers' Convention.

BY HERMAN F. MOORE.

[Continued from page 342.]

Dr. C. C. Miller gave a good talk on "Running an apiary for comb honey," after he had plenty of fun with the secretary about the article supposed to be lost in the mails, but which as a fact had been neither written nor mailed!

Mrs. N. L. Stow, of Evanston, the most experienced lady apiarist in our county, then read the following paper on the same subject:

Running an Apiary for Comb Honey.

I know that you do not expect any great amount of information, but only ask that I open the subject so that others may be induced to give their opinions. I shall not pretend to know just how an apiary should be run for comb honey, but would probably refer you to our bee-periodicals as an excellent source of information. With such good bee-literature as we have there is no excuse for ignorance; all that I know about bees has been learned by experience.

It is said that there is always something new to be learned about bee-keeping, so if I were to write an up-to-the-times essay I might tell you of many things that do not come in my experience; as my hives and fixtures were bought 15 years ago, the 10-frame hive made and sold by Mr. Thomas G. Newman at that time, you would probably call them out of date, but rather than to make kindling wood of them and give my good husband the further expense of buying more, I still use them.

In order that I may not take too much time, I will only touch upon the important points, as you follow, if you will make a mental note of such things as interest you, or that you can give or get information on, we can discuss them later.

Let us look at the subject and see what is involved in the question. There might be comparison, but I have no way of comparing, as I have never produced any other than comb honey. I judge it must mean more work, and at least closer attention than producing extracted honey, because I knew one who did all the work for his bees in the morning or evening, with an occasional holiday and perhaps Sunday; while I never dare be long away from home between the hours of 8 a.m. and 2 p.m., from the middle of May to the middle of July.

Wintering is a very important part of the subject, but that is a problem of itself, and properly comes under its own head. Locality is the same, but few of us can change our locality. Kinds of bees are more simple and easily controlled by the bee-keeper. Spring management is another part of the question, and also swarming, and hives, sections and section-cases, and last of all, selling; this part I like least of all, and gladly leave it to others.

Hives, sections, and cases are of most interest to the dealers I think, unless it is to the beginners, for it is worth while to start with the best, as hives and fixtures last many years. They may not affect the quantity of the honey produced, but they may affect the looks of the honey, and also the comfort in handling.

Having thus briefly disposed of a part of the subject, we have spring management and swarming to consider more fully. Supposing our bees to have been well wintered, and on the summer stands, the hives neatly arranged in rows, they should be inspected on the first day in spring warm enough for the bees to fly, or better, after they have had a good flight. The handling must be done quickly, as the bees having nothing to work upon now, may start to robbing, or if they are much disturbed they may ball their queen, and unless the day is quite warm the brood might become chilled. Usually it is only necessary to raise one or two of the outside frames to know the condition of the colony; it is better to do this early in the day so that the bees may have time to fly and get clustered again before the chill of the day comes on. If short of stores, frames of honey may be added, or candy put over the frames. The Hill's device may be removed now to keep the bees down on the brood, but the cushions should be left on. The entrances and floor of the hive should be cleared of dead bees, the entrance contracted, and then they should be left undisturbed until fruit-bloom, unless there is reason to think something is wrong. It may be profitable to put out rye or other meal for them to work on now, and water should be provided if not within easy reach.

In fruit-bloom I look them over thoroly, clip the queens if they are not already clipped, make a record of them, also the amount of honey and brood, and the general condition of the colony; remove division-boards, giving the full number of frames to the hive unless the colony is too weak to cover. The frames will contain honey if I have them; it is very necessary they should not be crowded, or short of stores now. Some years they will bring in honey all the spring, enough to keep up brood-rearing; they will gather from the bloom of the maples, elms, oaks, willows and locust, and from dandelions and fruit-trees, if the weather is right, but I have seen the time when they must be supplied up to June—not for stimulation, but to prevent loss of brood. This is the time when the bee-keeper must be alert and watchful; he should know exactly the condition of every colony; he should know every colony as he knows his own family, and he should build up the weak, supply the needy, note the queens whether prolific or not, and be able to distinguish between the good and bad traits that develop in the colonies, that when swarming-time comes one can be encouraged, and the other repressed. If there are many colonies, we will need besides sections a section-press and foundation fastener, and the hives must be all ready for the swarms, cases filled to put on as soon as there is lengthening of cells, and everything ready ahead of time rather than behind, for seasons vary so much that there is often two weeks difference in the time of doing the same work. If swarms issue very early I hive them on a new stand, giving the swarm the full set of combs, but if swarming-time has really come, and honey is coming in, I hive them on the old stand, with the hive contracted, and prevent after-swarms by the Heddon method, or occasionally by shaking off some of the bees from the combs in front of the new hive, and cutting out queen-cells.

If late in the season, I return the swarm in some way to prevent increase, the object being to keep the colony as strong in bees as possible until the honey-flow is over. There is much in Mr. Doolittle's idea of getting the bees at the right time; the strongest colony in the spring may waste its energies in rearing brood and swarming, and be outstripped in surplus honey production by its weaker neighbor, that with combs filled with brood just at the right time, are forced into the sections, and become so interested in honey-gathering that all its forces are kept busy and content.

Three section-cases to each colony, spring count, is usually enough for me for the season; the swarm may use two cases, and the old colony one. I usually put full sheets of foundation in for the swarms, and starters for the old colony. Contracting the brood-chamber during the months of June and July puts the white honey in the boxes, after that it is better to enlarge the brood-chambers and let the fall honey go into the brood-frames and secure young bees for wintering, and also save feeding. I have never failed to secure enough fall honey for wintering, so I try to get all the white honey in the surplus cases.

Before closing I must say a good word for the bee-es-

capas; they will pay for themselves in the comfort and ease with which honey can be removed from the hives. What was once to be dreaded becomes a pleasure thru their use.

It is impossible to lay down any set rules for the care of bees—one may have method and not be methodical, a system and not be systematic. So much depends upon the weather, season, and the condition of the colonies, that the plan that works well at one time, and even many times, may under slightly different conditions over which the bee-keeper has no control, and of which he may not be aware, result in a most disastrous failure. The bee-keeper must be competent to judge of what is best to do under varying conditions, or go slow until experience—the best of teachers—shall give him wisdom to decide.

MRS. N. L. STOW.

Then after some discussion of this topic, an adjournment was had at this point until 1:30 p.m.

AFTERNOON SESSION.

The first subject on the program was "Queen-Rearing for Small Bee-Keepers," by Mr. E. R. Root, who was expected to address the meeting, but failed to put in an appearance, owing to press of spring work. Mr. John Bodenschatz then read a paper on the subject, as follows:

Queen-Rearing for Small Bee-Keepers.

As the future of our colonies depends upon the prolificness of the queen we must endeavor to rear such queens from colonies that are noted for their prolificness, endurance and gentleness.

Take two colonies side by side in the same style of hive, of equal strength, and note results. You will find that one will produce nearly twice as much honey as the other. Why this is so is quite difficult to explain; altho the queen may be a good layer, and keep the hive crowded with her offspring, their honey-gathering and endurance may be lacking.

It is very important to improve our stock by rearing queens from the best colonies for increase of colonies, also to replace inferior queens. To do this, select several of the best colonies, one for the production of drones and the rest for the production of queens. The colony which is selected for the production of drones must have a very prolific queen, and workers famously noted as honey-producers. Place alternately two or three drone-combs in the center of the brood-chamber; about the middle of April, or near May, stimulate by feeding; by so doing we will have early drones from select stock. At the same time keep all drone-comb out of the inferior colonies.

To rear good queens stimulate by feeding, beginning in early spring so as to have the colonies in good condition by fruit-bloom. As we are aware, our best queens are reared thru the swarming-fever; this is because the brood-chamber is crowded with bees, to keep the combs warm, honey and pollen being plentiful, and large numbers of young bees emerging daily, which act as nurse-bees.

Having selected the colonies from which to rear queens, remove two or three frames of brood, replace with empty worker-comb. Look these over daily, and as soon as sufficient eggs are deposited in them, which should not exceed three days, place these combs alternately in a strong colony which was made queenless a day previous. Take out most of the unsealed larvae, contract if possible, also shake the combs containing young bees from other colonies in front of this queenless one. This will give an ample number of nurse-bees.

In about eight to nine days after furnishing the eggs to the colony made queenless, count the number of available queen-cells, make preparations for forming nuclei, and replacing queens accordingly. The same day destroy the queens from such colonies as are worthless. The next day, with a sharp penknife, cut out the queen-cells with a small amount of comb adhering. Care must be taken so as not to injure the queen-cells.

To introduce a cell into a colony made queenless the previous day, insert it into its natural position between two combs in or near the center of the brood.

For forming nuclei place in an empty hive, two combs containing brood in all stages, place the queen-cells between these two combs, add more empty combs and contract, also shake the bees from other colonies in front of the nuclei.

After these nuclei are formed, care must be taken so the queens will not get lost on their wedding flight. There must also be a contrast between these nucleus hives; this

can be done by placing boards in different positions in front of the nuclei.

It sometimes happens that the honey-flow slackens; great care must now be exercised with these small colonies, as the strong colonies will make it their business to hunt up the weak ones and deprive them of their stores.

When little or no honey is coming in, feeding must be resorted to; this must be done in the evening, the entrance contracted, and not a drop of honey left lying loose in the apiary.

It will also be very difficult to have over two-thirds of the queens fertilized.

Good queens can also be reared from a colony that has sent forth a swarm, but this should be discouraged as much as possible. I believe that in time to come the swarming habit can be bred out, and a non-swarming race established.

JOHN BODENSCHATZ.

After discussion the next topic on the list was "Running an Apiary for Extracted Honey." There was not much discussion of this topic, owing to lack of time. The most interesting and entertaining feature of the day's program was the question-box, which was opened in a most interesting and effective manner by Dr. C. C. Miller. After this an adjournment was had to the first Thursday in June, 1899.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Hiving Swarms in Shallow Boxes.

H. Lathrop's plan (page 278) of hiving swarms in shallow bodies looks quite well to a novice. I wonder if there will not be considerable swarming out from a brood-chamber of this size. What is your opinion? OREGON.

ANSWER.—In Mr. Lathrop's locality I think there will be very little trouble from swarms issuing from the small hives in which the swarms have been put. If there should be a continuous harvest till late in the fall it might be a different thing. In any case there will not be the same danger of swarms that there would be if bees wintered in such hives.

Bees After Salts, Probably.

I notice quite a number of bees all the time around where urine is put. What do they gather there? MD.

ANSWER.—Probably salts contained therein. Some make a practice of keeping the bees supplied with drinking-water slightly salted, and it is probably a good thing.

Limiting Swarming—Best Size of Hive.

1. I keep a few colonies of bees, which swarm too much. Can I stop that? If so, how? OREG.
2. What size hive do you think is the best? OREG.

ANSWERS.—1. You can probably limit them to one swarm each. When the prime swarm issues, set it in its new hive on the old stand, putting the old colony close beside it. A week later, set the old hive on a new stand at some distance, moving it at a time of day when the most bees are flying. The field-bees will return to the swarm, and so weaken the old colony that it will not be likely to swarm again.

2. That's a very difficult question to answer, and you will do well to read over all that has been said about it in past numbers of this journal, for much has been published. If you give the closest attention to your bees, it may be that

the 8-frame dovetailed hive, either one-story or two-story, may be best, but a larger hive, and perhaps a larger frame, may be better for bees that are left without much attention.

Bees Outside the Hive and on the Ground.

The alighting-boards are covered with bees all the time; they remain out over night, and if it rains they make no attempt to go in. They are crawling on the ground for several feet around the hive, and seem to be too weak to fly. The honey in the hive is candied. They have been acting so only for a few days. It has been very wet and cold for bees this spring. IDAHO.

ANSWER.—From the description it appears very like a case of starvation. Possibly the bees had worked all the liquid part out of the honey, and it was so cold they could not fly out for stores. Still, it seems that in a wet time they might have gotten water enough to use the granulated honey. If the bees were swollen, shiny, and trembling, it was paralysis.

Making Honey-Vinegar Old Combs of Honey.

1. I have a few bits of broken combs, honey and cappings of last fall's extracting, and as I will have more at different times, I wish to know how to work them into vinegar as they accumulate.

2. I have a few frames of sealed honey of last year's gathering, so thick that I cannot extract it without breaking the combs. How would you use it, or what is best to do with it? I wish to save the combs if possible. MISS.

ANSWERS.—1. Put them into a crock, cover with water and let soak a few days (no harm if a few weeks), then drain off or strain out the liquid, and let it sour as you would cider.

2. Perhaps the best way, if you want to save the combs, is to spray or sprinkle with water, then give to the bees to clean out, wetting again if necessary.

Bees from the Public Road—Size of Dadant-Langstroth Hive.

1. How far must bees be put from the public road?
2. What hive is the Langstroth-Dadant hive? ILL.

ANSWERS.—1. So far as any law is concerned, I think there are not many places in this country where there is any legal restriction as to distance. If bee-keepers are wise, there never need be any. Every one should put his bees so far from the road that there need be no sort of danger to passers-by. If a high fence is between the bees and the road, they may be put close to the fence.

2. I think the Dadants do not have any special Langstroth form. They use mostly, if not altogether, the Quinby hive, which has frames 18½ x 11¼.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 50 cents; 50 for 70 cents; 100 for \$1.25; 250 for \$2.75; 500 for \$4.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

The Premium offered on page 254 is well worth working for. Look at it.

GEORGE W. YORK, Editor.

GEORGE W. YORK & COMPANY,

118 Michigan St., Chicago, Ill.

ONE DOLLAR A YEAR.  SAMPLE COPY FREE.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

JUNE 8, 1899.

NO. 23.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Comb Honey 1820 Years Old.—Mention is made in the British Bee Journal of relics from the ruins of Pompeii, now in the public museum at Naples. Loaves of bread, also figs rather shriveled, and pears certainly no longer juicy. "But perhaps the most interesting relic in the room is a honey-comb, every cell of which can be distinctly made out. It is so well preserved that it is hard to realize that the comb is no longer wax, nor the honey, honey. A piece of the comb seems to have been cut out, and one can imagine some young Pompeiiian having help't himself to it and sitting down to eat it, when he had to jump up and fly for his life. One cannot help wondering what became of the piece, whether the young fellow took it with him and ate it, or whether he left it on his plate, intending to return for it when the eruption was over."

Rate of Fare to the Philadelphia Convention.—We received the following communication from Secretary Mason just a little too late for our last issue:

STA. B, TOLEDO, OHIO, May 25, 1899.

EDITOR AMERICAN BEE JOURNAL.

I've been wondering what kind of an animal you take me to be, anyhow. On page 296 I corrected the statement made in your quotation from the Chicago Record as it appeared on page 264, and in your comments you say of the Record, "And it may be they are not so far wrong as they might be." Of course, a person doesn't have to be an editor

to know that, but sometimes there is quite a difference between "one fare for the round trip" and two-thirds of that amount. And then, you say, "at any rate there is plenty of time yet to announce the rates, The important thing for bee-keepers to do is to begin now to arrange to be in Philadelphia," etc. Well, now, if railroad rates are not *the* "important thing," I wish "ye editor" would just post "your humble servant," and the rest of your readers, as to what "the important thing to arrange" for is, and we'll try and get down to business.

If it is not important to know about rates there may be plenty of time yet, but if rates *are* important (and who doubts it?) the sooner we can know about them the better. It's now too late to get a notice in the June bee-papers, and it's possible we may not know the rates in much of the territory covered by the Association in time even for the July journals.

I have corresponded with all of the passenger associations—six in number—and up to May 17 two only had fixt the rate of fare—the Central Passenger Association and the Trunk Line Passenger Association. The New England, Southeastern, Southwestern, and Western Passenger Associations had not fixt rates, but it is probable that the New England Association will fix the rate at one fare for the round trip.

When I sent the communication that appears on page 296, I *thought* I was doing your readers (if not *you*) a favor, and the same thought calls this out, but if you've any more reliable information than I, please give it, as it may be needed, but don't give us "maybe's," for they "may be" misleading.

A. B. MASON,

Secretary United States Bee-Keepers' Association.

Well, Doctor, we fear you are borrowing trouble. Did you ever know the G. A. R. to fail to get good railroad rates to their annual encampments? We never did.

Of course, the railroad rate is a *very* important thing—especially to some of us editors who have to go nearly 1,000 miles to the convention. But we expect to be satisfied with whatever rate the G. A. R. secures, for we feel pretty certain it will not be over half as high as the rate bee-keepers alone could possibly get.

Don't you get weary in well doing, Doctor. Just keep on sending your "favors" this way, and we will try to appreciate them. But don't get discouraged when we are trying to help things along, even if our little help doesn't help very much. You see, we'll have a lot of time to learn yet, if we should be blest with as many years as you have lived to enjoy. And may you be with us many years more.

Spring Management of the right kind, says Editor Hutchinson, in the Bee-Keepers' Review, is the foundation of our honey crop. Colonies sometimes starve in the spring, or are greatly weakened or retarded in breeding by a lack of stores. Mr. H. G. Sibbald, of Ontario, puts combs of honey outside a division-board, and has it so arranged that the bees can have access to these combs. This removes all danger of starvation, and greatly encourages the rearing of brood. At the end of the fruit-bloom he puts the outside combs of honey in the center of the brood-nest—first one, and then in three or four days the other. He scratches the surface of the combs. This plan converts the early dark honey into bees.

Talking Bees to School Children. The following item appeared Saturday, May 27, 1899, in The Chicagoan—a local weekly newspaper published in the suburb of Chicago where we live:

"A rare treat was given to the eighth-grade pupils of the McPherson school last Thursday afternoon, when Mr. George W. York, editor of the American Bee Journal, gave them an illustrated lecture on bees. The pupils were delighted, and the way Mr. York described the simple animal was truly wonderful."

The only excuse we have to offer for reproducing here this appreciated notice, is to suggest that bee-keepers in other cities will find the school children greatly interested

in a talk on bees if given a chance to hear it. We had a Langstroth frame of bees in a glass hive, and gave therefrom a practical illustration of the work of bees in the hive. On the comb were worker-bees, drones, and a queen. There were capt worker-brood, drone-brood, and the beginning of a queen-cell. In the open cells were honey, eggs, larva in various stages of development, and pollen.

We also had a chart illustrating the development of bees, and some other things in relation thereto.

Mrs. Lane, the efficient teacher in the eighth grade of the McPherson school, had invited us to visit them and give the bee-talk, expecting to have the pupils take notes and write out afterward as much as they could remember of what we said. The best reports were then to be published in their little school paper. It made a splendid written exercise for the pupils, and the talk seemed greatly enjoyed by them, many asking a number of questions, which showed that they were much interested.

Live bees in a glass hive are always interesting even to people who are far beyond their school-days.

Preventing Swarming.—This item, copied without note or comment in the Australian Bee-Bulletin from the New Zealand Farmer, makes one wonder whether bees are so different on opposite sides of the globe, and whether bee-keepers are so much more skillful on that side:

"There is only one way of absolutely preventing swarming, and that is to take out every frame in the lower story at least once in every seven days, and destroy every queen-cell that the bees may be building. The job, to many, may seem a tedious one, but it is really very little trouble. An expert bee-keeper ought to be able to take out each of the ten frames and destroy every cell in about five minutes."

Destroying all queen-cells once a week will hardly prevent swarming if bees sometimes swarm with no queen-cells present; and the man that can handle each comb and miss no queen-cells when averaging only 30 seconds to a comb must be expert indeed. But sometimes those who write for agricultural papers about bees are more theoretical than practical.

Bee-Keeping in Chili.—Gleanings recently contained the following paragraph referring to an article which appeared lately in the American Bee-Keeper:

An interesting letter from Chili, by the editor of the Chilean Bee Journal, is given, together with a picture of the writer, Mr. Lafitte himself, and two Chilean apiaries. His journal comes here, and I have noticed with much pleasure the excellent and progressive qualities of it in every respect. He says the general aspect and climate of Chili are especially adapted to bee-keeping. Some of the farms cover 40,000 and some 80,000 acres, and some are 30 or 40 times as large as that. There is an enormous consumption of wax there for tapers in the Roman churches. One of the largest apiaries consists of 700 frame hives, 400 of which are of the Dadant-Blatt system, and about 300 of the Langstroth-Simplicity style. These 700 hives are divided into five apiaries, about two miles apart. So far as harvests are concerned, 110 pounds per hive is the most that has been extracted. This was an apiary of 100 Dadant-Quinby hives. Deep frames are inconvenient in a climate like that of Chili.

Getting Queens from Italy by Mail is reported a success in Gleanings. The A. I. Root Co. send to the Italy breeders queen-cages prepared with Good candy and sealed honey, all ready to put in the bees, and out of a dozen queens sent ten came thru alive, but one of the ten was weak.

Cuban Bee-Keeping is Expensive, according to Gleanings, as the hot climate makes sheds almost imperative, and they cost a good deal of money.

Getting Bees Started in Sections.—Editor Hutchinson speaks approvingly of the plan of first putting on extracting-supers, and Editor Root advises that the experiment be tried of putting on a shallow extracting-super, and then when the bees are fully at work taking away the extracting-super and putting on a super of sections.

Mr. B. WALKER, of Osceola Co., Mich., has been in Tennessee for several weeks buying carloads of bees—475 colonies in all. He is sending them into Michigan, where he runs some ten apiaries every year.

DR. A. B. MASON, of Lucas Co., Ohio, Secretary of the United States Bee-Keepers' Association, writing us May 25, reported thus concerning the weather and his bees:

"This is the first real, nice day for bees since the nice weather we had in April, but there are no blossoms for them to work on. I have full supers on several hives, and half supers on most of the others—not for storing honey, for there is none coming in, but to give room for the bees; but to-day I notice that nearly all the honey has been carried from the brood-nest into the supers, and the brood-combs are full of brood."

THE HUMANE ALLIANCE, New York (50 cents a year), is a popular and interesting magazine devoted to animals and pets and humane education. The May number is remarkable for its fine illustrations and the great amount and variety of interesting matter in relation to animals. It also says that there is one subject on which every dictionary, encyclopedia, natural history and zoology is in error; that is, where the subject is treated fully. It is strange that this error is in the description of one of our native American animals, the armadillo, of which little seems to be known, tho this animal is likely to become a valuable pet.

MR. W. A. PRYAL, of Alameda Co., Calif., writing us May 15, had this to say:

"Mr. Pender, of Australia, arrived in San Francisco Saturday morning from his eastern trip; he stopt at Los Angeles and saw Mr. Martin. He reports the country very dry in the southern portion of the State. He called on me Saturday evening. I askt him to take dinner with me Sunday, and he did so. I drove him about Berkeley, and showed him over the grounds of the State University, and also thru the grounds of the institution for the deaf, dumb and blind, which is also at Berkeley. He'll replenish his cages with young bees at my place to-morrow, and the next day he takes the steamer for Australia."

MR. R. MCKNIGHT, for years a prominent bee-keeper of Ontario, Canada, has a most beautiful home, as is shown by the two nice pictures in the May Bee-Keepers' Review. He says this in reference to it:

"The grounds embrace about 4½ acres—and they are admitted, I believe, to be the finest site in town. They cost me \$10,000. When Mr. Hooker, of London, was staying with me during the Chicago Fair, we were one evening sitting on the rustic seat in the distance, when he declared he had witness no finer prospect in all his travels in Europe. Mr. Cowan was also much taken with the situation. Mr. and Mrs. Cowan stopt with me for ten days during their first visit in 1887. My apiary was located in the orchard, which lies behind the house, and inside the row of ever-greens shown here. I have occupied this place for 23 years, and laid out the grounds, planted all the trees, shrubs, hedges, etc., which are now, like myself, getting old. I fear that my bee-keeping correspondence is about over. I have no bees at home now; not being able to attend to them. I still have an apiary about 15 miles from here; but I do little in it personally."

Hildreth & Segelken, JOBBERS AND COMMISSION MERCHANTS.....

HONEY, Beeswax, Maple Sugar and Syrup.

120-122 W. Broadway,
NEW YORK.

We desire to inform our friends and patrons that our firm has been re-organized and additional capital added. The business will be conducted under the firm name and style of

HILDRETH & SEGELKEN,

at the old stand, where we have had the pleasure of serving our friends for the past 11 years. Management and supervision will be the same and our business methods—those of square and honest dealings—will be practiced as heretofore.

We believe we have won the esteem and confidence of our shippers throughout the country, and that our dealings, as a rule, have been of the most pleasant nature.

Our additional capital will put us in position to increase our already large business still farther, if possible, and at the same time enable us to treat our shippers even more liberally than heretofore, in making advances, etc.

Records will show that we handle by far the bulk of all the honey sent to our market. We make honey the principal part of our business, are personally acquainted and have trade connections all over the country, which enable us to handle any amount of honey to better advantage than any other house.

Old shippers know us and will bear us out in what we have said. Those bee-keepers who do not know us and have had no dealings with us, we would cordially invite to correspond with us and make our acquaintance. We not only handle on commission but buy largely as well, from small lots to carloads, for spot cash.

We wish to call the attention of the Southern bee-keepers to the fact, that our market never was in better condition than this season. Old stock is disposed of and the market is bare, with a good demand. New crop will find ready sale and at higher prices than have ruled for years past. We would advise them to send their honey, while there is a good demand at good prices, as later on conditions of the market may change.

We also handle MAPLE SUGAR AND SYRUP very extensively, and would be pleased to hear from those having any of these goods to offer.

In conclusion, we wish to extend our thanks to all of our shippers for their past favors, and trust to receive their kind consideration in the future.

21A4t Please mention the American Bee Journal.

Queen-Clipping Device Free....

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year

and the Clipping Device. Address,
GEORGE W. YORK & COMPANY,
118 Michigan St., Chicago, Ill.

The Midland Farmer

(SEMI MONTHLY.)

The representative modern Farm Paper of the Central and Southern Mississippi Valley. Page departments to every branch of Farming and Stock-Raising. Plain and Practical—Seasonable and Sensible. Send 25 cents, silver or two-cent stamps, and a list of your neighbors for free samples, and we will enter your name for 1 year. If you have not received your money's worth at end of year, we will, upon request, continue the paper to you free of cost another year.

Italian Bees and Queens

... FOR SALE ...

Queens, \$1.00 each. Bees by the pound, \$1.00. Nuclei, two-frame, with Queen, \$2.00; one-frame, \$1.50; each additional frame, 50 cents. These are sent in light shipping-boxes, L. pattern frames.

MRS. A. A. SIMPSON,

1914t SWARTZ, Greene Co., PA.

PUPS FOR SALE

PURE ST. BERNARD PUPPIES CHEAP.
6 weeks old. H. S. JONES,
23A1t Mayfair Apts., MAYFAIR, ILL.

In the multitude of counsellors there is safety.—Prov. 11-14.

Best Use for Empty Combs.

Query 01.—In case you had 150 or 200 nice, straight, empty worker-combs, had 50 or 60 colonies of bees, desired as little increase as possible, and was producing mostly comb honey, what, in your judgment, would be the best and most profitable way to use those combs?—HOOSIER.

W. G. Larrabee—I should use them for increase.

Mrs. L. Harrison—Use them for extracted honey.

E. France—I would put the combs with bees enough to work them.

Engene Secor—Melt them into wax, and trade for foundation to use in sections.

Adrian Getaz—If the combs are white, cut them up and fit them in the sections.

Dr. A. B. Mason—I would use them in supers with the colonies I run for extracted honey.

P. H. Elwood—Make enough increase to cover the combs, and nrite in the fall or spring.

E. Whitcomb—Sell them to some enterprising fellow who produces extracted honey.

Mrs. J. M. Null—I do not know of any use except in the way of increase, which I should desire.

G. M. Doolittle—By "pruning" out the 150 to 200 poor combs that may be found in

Extracted Honey Wanted

As soon as you have any good, well-ripened Extracted Honey for sale, send us a small sample, stating quantity, price expected delivered in Chicago, and how put up. Prefer it in 60-pound tin cans. Expect to be able to place carload lots as well as smaller shipments of Extracted Honey. But don't ship us any until we order. Address,

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

your 50 or 60 colonies, and using the "nice, straight, empty worker-combs" in their places.

J. M. Hambaugh—Breed up your bees before the harvest. Populous colonies will produce the honey.

Dr. C. C. Miller—They could be used for increase, for extracting, or to give extra room before and after the harvest.

Rev. M. Mahin—I would substitute some of them for any crooked or defective combs in the 50 or 60 colonies. The rest I would melt into wax.

Chas. Dadant & Son—Use a part of them to exchange for whatever drone-comb might be in your colonies, and hive swarms on the balance.

Dr. J. P. H. Brown—I would use them to the best possible advantage in the "little increase," and to replace bad comb in the other colonies.

R. C. Aikin—For extracting. If no increase, what else can you do with them? If you can use it that way, have them filled for use in feeding.

Jas. A. Stone—I should make up my mind to go into extracted honey, and use them above queen-excluders; or else I would make them into beeswax.

J. E. Pond—Sell them for the best offer you can get. I assume, however, that your colonies are all amply provided with combs, and that these are extra and not needed.

Emerson T. Abbott—Let the bees swarm, and hive the swarms on the old stand on the combs, and give the swarm plenty of surplus room at once. Move the old hive away.

O. O. Poppleton—Unless there are strong reasons why you should not increase your production of extracted honey, you might do that. Such combs would be of much value used that way.

Prof. A. J. Cook—Melt up the poorest ones—those with drone-cells and not straight—which would not be required. But why not increase? If one is keeping bees why not utilize all the combs?

C. H. Dibbern—That would depend a good deal upon the season. If the prospect for surplus was good, I should do all that I could to keep back swarming, but should use up those combs to some extent for hiving swarms.

A. F. Brown—If I do not want increase I should use the combs over a few colonies and run them for extracted honey. It is presumed you have already replaced all drone combs in your colonies, and have these combs left over.

C. Davenport—First, if there were any ill-shapen or drone-combs in the hives occupied I would replace them with some of those straight worker-combs. Here, in an ordinary season, what increase could hardly be avoided from that number of colonies would use up the rest, or all of them.

G. W. Demaree—I should use them to catch the fall flow of honey, because at that time of year, in my locality (Kentucky), bees do not succeed at comb-building. But if I lived in a locality where there was no fall bee-pasture, I would render into wax the inferior combs, keeping the best for any emergency.

D. W. Heise—If little increase is desired, and mostly comb honey is to be produced, and if the 50 or 60 colonies are already supplied with as good combs as the empty ones are, I would sell my surplus combs. Failing to secure a price equivalent to the value of the wax that said combs contain, I would melt them up, and use or sell the wax.

Mrs. A. J. Barber—I should hive my swarms upon them, putting four to six into the new hive at the sides; fill up the middle with new frames with one inch starters. Put the hive that cast the swarm to one side, and when others swarm pile them on it five or six high. This will make a line colony before winter, and does not increase much.

R. L. Taylor—I should use them first for the extracted honey so far as needed, then

SWEET CLOVER

use some for honey to furnish stores of such colonies as needed them, and for feeding next spring, and the rest for swarms, giving each swarm but two or three in the center of the brood-chamber, or if more had to be given to use them all, restrict the brood-chamber to the size of five Langstroth frames.

E. S. Lovesy—If I were in your position, with a desire as you express it, I would divide the bees just enough to take the swarming fever out of them, then I would take about 10 colonies and run them three stories high for extracted honey, using those combs for all they would be worth. Then I would run the remainder for comb honey. Of course, a good honey-flow would be the main condition to success.

S. T. Pettit—I would put the first swarms upon them until about two-thirds of them were used in that way, then in 10 days after biving remove about one-third of the combs. Take those containing the youngest brood, and then fill up with empty combs. Those combs of brood can be used in different ways. Or I would hive swarms upon them in contracted brood-chamber, and in ten days remove the dummies spread the brood, and insert empty combs. Every swarm thus treated will render good service.

Bees Doing All Right.

My bees are doing all right at present, but they had a hard winter. I lost 5 colonies out of 32. They are booming now. I had my first swarm to day (May 22). Nearly all the bees are dead in this part of the country. There is a good outlook for a honey-flow here this season. It has been cold for a few days, but it is warming up now. H. MESSER.

Greene Co., Pa.

A Destructive Hailstorm.

We have just had one of the most furious hailstorms in this locality ever known. The hails were not of such unusual size, but they came with such force and so many as to make it quite destructive. Bark was knocked off of young trees, and the marks of hail are plainly visible on the bee-hives. Some of the farmers are plowing up their wheat to add a "buck" thereto, so bees will fare all right in the fall.

H. G. QUIRIN.

Erie Co., Ohio, May 31.

Hard on the Farmer or Producer.

EDITOR YORK:—I desire to thank you many times for publishing the article by G. M. Doolittle, entitled, "Prices of Honey not Made by Law(?)." I have often wondered if it could be possible that no one of the many able writers and thinkers of the Bee Journal knew the real cause of the decline of prices, not only in honey but in everything else. I could hardly believe it, when I saw that Dr. Miller when asked the cause of declining prices of honey, wiggled out of it by practically saying, "I don't know."

I do not wish to set myself up as a teacher, or anything of the kind, but it is so simple to my mind that I think surely our great bee-keepers could easily give us the reason. A system that will allow the producer only a small portion of the value of his product cannot thrive and exist any great length of time—it will surely work or bring forth its own downfall, for if the producer gets only a small portion of the value of his product, he cannot then buy what he really needs, and there being taxes, rents and interests (besides the profits that the other fellows get) to pay, he does without a great many things that are necessary to make life pleasant. A system that produces million-

aires and paupers is surely not a just one. A system that causes the toilers and laborers to go hungry, and causes those who do no real labor at all to get immensely rich, is by no means in accord with the teaching of Christ. A system that will cause little, innocent children (who have never wronged any one) to go without food, clothing and shelter, when others not a whit better have all the luxuries that human mind can devise and make, is certainly very unjust, and will not forever be tolerated by a just God and a civilized people.

It almost makes my heart bleed when I see little children go barefooted, and with an almost empty stomach, whose parents have toiled by night and by day and are unable to provide for their dear ones. To me it is hard to see how a Christian people can stand idly by and let such a condition of affairs go on unhindered. If we all got what we justly earn, the editor would not have to wait for months and months for the money due him for his paper, but when it is toil, toil, toil, by day and by night, and not get enough to have a decent place to live, and good food and plenty of it to eat, and good clothes to wear, it is hard to find enough spare cash to pay for a paper, altho we desire very much so to do. Always hoping for better times, but finding that the rent or interest and taxes increase but wages go down, and the price of what we produce seems to get less and less, and the times get harder. F. H. JOHANNING.

San Bernardino Co., Calif., May 7.

Did Well on Fruit-Bloom.

I have 6 colonies of bees in good shape. They did well on fruit-bloom, and have built up strong for white clover, this being our main stand-by for honey. It has been cool the last week, with a good show for frost. We had a hailstorm the 17th; there was hail bounced off my bee-hives as large as hen's eggs, leaving their marks on the roof, and calling the bees out to see what was the matter.

The winter loss was heavy here, and in

Superior Stock.

Every bee-keeper who has had experience with several strains of bees knows that some are far superior to others, that there is scrub stock among bees, just as there are scrub horses, cattle, sheep and poultry. Let me give my own experience:

Years ago, while living at Rogersville, I made a specialty of rearing queens for sale. Before engaging in this work I bought Italian queens and Italianized, not only my own bees, but all within 3 miles of my apiary. In buying those queens I think that I patronized nearly every breeder in the United States; and even in those years of inexperience I was not long in noting the great difference in the different strains of bees. The queens from one particular breeder produced bees that delighted me greatly. They were just plain, dark, 3-banded Italians, but as workers I have never seen them equaled. They seemed possess of a steady, quiet determination that enabled them to lay up surplus ahead of the others. Easier bees to handle I have never seen. It sometimes seemed as tho they were too busy attending to their own business to bother with anything else. Their honey was capt with a snowy whiteness rivaling that of the blacks. In addition to these desirable traits must be added that of wintering well. If any bees came thru the winter it was the colonies of this strain. They came as near being ideal bees as any I have ever possessed.

All this was 20 years ago; and several times since then I have bought queens of this same breeder, and I have always found this strain of bees possess of those same good qualities—industry, gentleness, and hardiness. In addition to this they cap their honey as the blacks do theirs. I have frequently corresponded with this breeder, and with those who have bought queens of him, and I am thoroly convinced that he has a strain of bees that are far superior to the general run of stock. If I were starting an apiary, for the production of honey, I should unhesitatingly stock it with this strain of bees.

This breeder has always advertised in a modest, quiet, unassuming sort of way, nothing in proportion to what the quality of his stock would have warranted, and at last I have decided that I can help him, and benefit my readers, at a profit to myself, by advertising these bees in a manner befittingly energetic.

The price of these queens will be \$1.50 each. This may seem like a high price, but the man who pays it will make dollars where this breeder and myself make cents; and when you come to read the conditions under which they are sold, it will not seem so high. The queens sent out will all be young queens just beginning to lay, but, as there are no black bees in the vicinity, it is not likely that any will prove impurely mated. If any queen SHOULD prove to be impurely mated, another will be sent free of

charge. Safe arrival in first-class condition will be guaranteed. Instructions for introducing will be sent to each purchaser, and if these instructions are followed, and the queen is lost, another will be sent free of charge. This is not all; if, at any time within two years, a purchaser, for any reason WHATSOEVER, is not satisfied with his bargain, he can return the queen, and his money will be refunded, and 50 cents extra sent to pay him for his trouble. It will be seen that the purchaser runs NO RISK WHATSOEVER. If a queen does not arrive in good condition, another is sent. If she loses her in introducing, another is sent. If she should prove impurely mated, another is sent. If the queen proves a poor layer, or the stock does not come up to the expectations, or there is ANY reason why the bargain is not satisfactory, the queens can be returned and the money will be refunded, and the customer fairly well paid for his trouble. I did not make this last promise if I did not KNOW that the stock is REALLY SUPERIOR.

I said that the price would be \$1.50 each. There is only one condition under which a queen will be sold for a less price, and that is in connection with an advance subscription to the Bee-Keepers' Review. Any one sending \$1.00 for the Review for 1899 can have a queen for \$1.00; that is, I will send the Review for 1899 and one queen for \$2.00. Of course, this special offer is made for the sake of getting the Review into the hands of those who are unacquainted with its merits.

Orders for these queens will be filled strictly in rotation—first come, first served.

many cases was the fault of the bee-keepers, in my estimation. I think if they would read good bee literature instead of trusting to their own superstitious ideas often, and put to practice what they learn, they would profit by it. Success to the Bee Journal. P. W. GREGOR. Wayne Co., Ohio, May 22.

Good Prospects for Honey.

It has been very severe on plants and trees, but white clover has stood it all right, as the whole country seems covered with it, and also the clover of last season's seed is coming up thick. The prospects are good for a fine crop of honey. My bees have begun swarming—the first swarm issued May 8, which I think is pretty early, as bees came out of winter quarters rather weak, and a great many died this spring. E. A. DONEY. Scott Co., Iowa, May 25.

Honey-Dew—Bees in Fair Condition

EDITOR YORK:—Enclosed you will please find a clipping from the Farm Journal, in which a man offers \$5.00 for one pound of honey-dew from aphides. I think Prof. Cook ought to get after that fellow and collect the reward. Bees are in fair condition. I put 149 colonies into the cellar Nov. 25, 1898, and took them out April 10, 1899. They dwindled down, and I have doubled up to 129 colonies. Prospects are for a good season. La Crosse, Wis., May 8. C. F. LANG.

[The item on honey-dew, referred to by Mr. Lang, reads as follows:—Ed]

HONEY-DEW.

I make no great pretensions to knowledge, but having lived all my life in the woods of southern Indiana, I have had a chance to learn something of this much-talkt-of honey-dew, and I am free to take the ground that there is no such thing, and I will give any man five dollars on receipt of one pound of honey that can be proved to have been gathered from deposits of aphides. Next summer, say the last of June or during July, when the weather is warm and moist, what is generally called splendid growing weather, take a trip out into the woods in the afternoon, climb up into an oak, hickory or ash tree and examine the leaves, and you will find small particles of a dried substance on the leaves. Be sure to have a glass with you, and you will find a small rupture on the top side of the leaf, showing that the substance dried on the leaf has exuded from it. Now touch your

tongue to this dry substance, and you will find it sweet as sugar, and on the ash, hickory, poplar, pear and maple you will find it of a pleasant flavor, but on the oak it will not be so pleasant. At that time you will find no bees working on the leaves, but early the next morning return to your investigation and you will find those same trees alive with bees, provided there was a fall of dew the night before, as this substance must be dissolved before the bees can handle it.

In localities here, where no oak or black-gum timber grows, we get no better honey than is gathered from the so called honey-dew. The two kinds mentioned seem to make it very dark. D. M. R. Lovett, Ind.

Convention Notice.

Texas. The Central Texas Bee-Keepers' Association will meet at Milano, Tex., July 20 and 21, 1899. All are cordially invited to attend. H. H. HYDE, Asst. Sec. and Treas. Hutto, Texas.

Farm Wagon Economy.

The economy of this proposition is not all found in the very reasonable price of the wagon itself, but in the great amount of labor it will save, and its great durability. The Electric Wheel Co., who make this Electric Handy Wagon and the now famous Electric Wheels, have solved the problem of a successful and durable low-down wagon at a reasonable price.

ELECTRIC

This wagon is composed of the best material throughout—white hickory axles, steel wheels, steel hounds, etc. Guaranteed to carry 4000 lbs.

These Electric Wheels are made to fit any wagon, and make practically a new wagon out of the old one. They can be had in any height desired and any width of tire up to 8 inches. With an extra set of these wheels a farmer can interchange them with his regular wheels and have a high or low-down wagon at will. Write for Catalog of the full "Electric Line" to Electric Wheel Co., Box 16, Quincy, Ill.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, May 8.—Not anything of consequence doing; a little honey is being sold at prices that have been prevailing for some time. White comb is scarce, but there is a surplus of dark. Extracted unchanged. Stocks light. Beeswax, 27c. R. A. BURNETT & CO.

NEW YORK, May 9.—Fancy, 70-72c; choice, 60-62c; fair, 51-52c; common, 35-40c per gallon. Beeswax quiet at from 20-28 cents, according to quality.

Our market is in first-class condition, being here of extracted honey, and demand good. New crops is beginning to arrive from the South. Comb honey is well cleaned up; some demand for white but demand for dark has ceased.

HILDRETH & SEIGELER.

SAN FRANCISCO, May 24.—White comb, 10@10 1/2c; amber, 7 1/2@9c. Extracted, white, 7 1/2@7 3/4c; light amber, 6 1/2@7c. Beeswax, 26 1/2@27c.

Prices for 1898 product remain nominally unchanged, with stocks light and in hands of jobbers. Values for this year's honey have not yet been established, but are almost certain to rule lower than the jobbing rates now current for old. This year's California crop is expected to aggregate 200 carloads, 75 percent of which will be from San Joaquin Valley and mainly alfalfa honey.

BOSTON, May 17.—Fancy white, 12 1/2@13c; A No. 1, 11@12c; No. 1, 10c; light amber, 9c; buck-wheat, 8c. Extracted Florida, white, 7 1/2@8c; light amber, 6 1/2@7c. Beeswax, 27@28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices, quoted would be shaded some, but as stocks are a little heavier than is liked at this season of the year.

BLAKE, SCOTT & LEE.

KANSAS CITY, May 15.—No. 1 white comb, 15c; fancy amber, 14c; No. 1 amber, 13 1/2c; fancy dark, 13c; No. 1 dark, 12c. White extracted, 6c; amber, 5 1/2c; dark, 4@4 1/2c. Beeswax, 25c.

C. C. CLEMONS & CO.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 12@12c; some very poor selling at 6@7c, and dull. No more business in honey before the opening of the ensuing season.

BATTERSON & CO.

OMAHA, June 2.—A few little lots of new honey from Texas have made their appearance on the market. The stock was put up by inexperienced people and only sold at moderate prices. Extracted of fairly good flavor brought 5 1/2@6c. Comb honey put up in 60-gallon cans and filled with extracted, sold at 6 1/2c. This is a most undesirable way of packing comb honey. Trade does not care for it. PEYCKE BROS.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10@11c; dark and amber, 8@9c. Extracted in fair demand without change in price. Beeswax, 25@26 1/2.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey. M. B. HUNT.

WHEN YOU WANT Send us your order. We will fill it by RETURN MAIL with the best of ..QUEENS.. Italians, large yellow queens, healthy and prolific, workers gentle and the best of honey-gatherers. CONTRIBUTED ARTICLES

The Notre Dame Bee-Hive and Wintering Device.

BY B. J. CHRYSOSTOM.

ALMOST any box, or hive containing loose frames with space enough between the ends of the frames and hive to admit a board say $\frac{1}{2}$ inch thick, can be converted into what in this locality is known as the "Notre Dame Hive," by means of a simple device consisting of the following pieces:

One strip of iron one inch wide, $\frac{1}{8}$ inch thick, and the depth of the hive; two holes much like key-holes are punched in it near each end. Four small screws to fasten this to the board, which is cut to fit in the end of the hive. Two or four 3×3 inch coach or wood screws, the points of which are cut off, and a groove cut near the end to fit in the slots in the strip of iron—a kind of little button which when in the slots will pull back as much as it will push forward. These screws, if only two, are put thru in the center of the end of the hive, and are so spaced that when the board is put on the slots in the iron strip will drop down in the grooves, cut in the screws, and rest on the bottom of the hive. If four screws are used then two are put opposite the second frame from the outside. The heads of the screws are flattened for convenience. Three little strips of wood are nailed on the sides and bottom of the inside of the hive against which the board fits up tightly when screwed up against the frames. One little strip of oilcloth is tacked on the end of hive and board; this is to prevent the bees from getting behind the board. The edges should be turned in so that no threads are visible for the bees to pull and bite. The holes for the screens are bored with a bit smaller than the screws, and a screw of the same size with

the point sharp is used to cut the thread in the wood, because the screw with the blunt point will not do the work.

The above description was promist last fall, but had been delayed till spring for the purpose of further testing the superiority of the Notre Dame hive in wintering bees on stores very largely composed of honey-dew.

Some were of the opinion that if the bees could be kept warm and dry, and have several flights during winter and early spring, the bad effects of poor food would be, to a great extent, obviated. Such has been the case in this particular instance.

Our experimental work in this line was considerably aided by the issuing of three small swarms, about the first of September, from some nuclei which had been formed for the purpose of rearing late queens. The swarms were hived on drawn combs and fed honey-dew; two of the swarms were made queenless late in the fall, and put in full-

The Notre Dame Bee-Hive and Wintering Device.

depth supers and placed over the parent colony or nucleus, thus forming one colony on 16 frames.

The other swarm was hived on 16 frames, two of which contained hatching brood, and was fed about 20 pounds of honey-dew. To-day (April 20) this colony is working

nearly as large a force as many of the old ones, is in excellent condition, and bids fair to rival the best.

Our bees are wintered on the summer stands in houses, built without any pretensions to warmth, merely affording a shelter from storm and wet. About the middle of last October the bees were warmly packed in short straw and chaff, by placing a board wall about eight inches from the rear of the hives, and filling this space and that in front and between the hives with a mixture of short straw and chaff. The space between the hives in some cases is two inches, and in others about five.

A strong cloth was put on the frames, and a full-depth super put on. Then one or two little woollen blankets, and then the super was almost filled with chaff over which a wirecloth was placed to keep the mice out; then more chaff, straw and forest leaves till all was entirely covered up. I believe that the bees never suffered the least from cold, because, so far as I know, the temperature of the packing never fell below 50 degrees. Measurements were taken from time to time with the following results:

Jan. 7—Thermometer outside 10 degrees above zero; in packing, 30 degrees above.

Jan. 19—Thermometer outside 12 degrees above zero; in packing, 42 degrees above.

Jan. 29—Thermometer outside 18 degrees below zero; in packing, 39 degrees above.

April 20—Thermometer outside 30 degrees above zero; in packing, 72 degrees above.

April 24—Thermometer outside 55 degrees above zero; in packing, 84 degrees above.

The uniformly high temperature in the packing is owing to the fact that there are no air-spaces around the ends of the frames, and the heat of the cluster radiates thru the walls of the hive and remains in the packing, thus protecting the bees and brood from the bad effects of sudden and severe changes in the weather. It is certainly a gratification to the bee-master, when he packs his bees snug and dry in the early fall, to know that they will not suffer from cold, and will need no further attention until the next May. It is also additional satisfaction, when wishing to look into a hive, to turn two thumb-screws and lift out the frames almost free of propolis.

I wish to state here that four screens to a hive would do the work better and more satisfactorily if two were placed opposite the second frames from the sides of the hive. Suppose we wish to expand the hive $\frac{1}{2}$ of an inch, which I think is sufficient to let the frames lift out, then we have only to turn each of the four screws so much, and the space is equal on both sides.

If the bee-keepers in cold countries desire a hive that combines in itself the advantages of the box for safe wintering, and the loose frame hive with its facilities of frame manipulation made more easy and agreeable, a hive in which bees will winter better, packed in a shed secure from storm and wet, without the trouble, expense, care and anxiety attendant on cellar wintering, then they might do well to invest a few cents in the "Notre Dame Device," put it in one of their hives, and give it a trial.

With this hive bee-keepers will have no need of beecellars nor chaff hives. Cheaply built sheds would be better, and if properly built would save the trouble of moving hives, and the business would be made more easy and pleasant because much of the work could be done in the sheds or houses on rainy days, as I have been accustomed to do for several years.

I have learnt by experience that to avoid the loss of queens and other inconveniences to the bees, their houses ought to be built octagonal in form, so that three hives face to the northeast, three to the east, three to the southeast, three to the south, etc., with a board about 2½ feet wide and about 3 feet high extending out from each corner so as to make the division complete, and also to serve as a protection from winds. There ought to be a window to each three hives set in on pivots, so as to open and close easily. When looking thru a hive all windows should be closed, and opened when thru the bees will then get out immediately. There is also room in this little house for surplus supplies, and a little corner to do the frame and section work. There are many advantages in this arrangement. It might be more profitable to keep 48 colonies in four such little houses in large hives (non-swarmling) than to keep 100 small colonies in a yard in small hives. However, this is a question better discussed by persons of long and successful experience, a subject on which I would like to read some thoughtful articles.

It is also important to have frames about five inches wide inserted in the wall against which the porticos of the

hives fit tightly, and so placed in the wall as to give about two inches incline outward to the hives, so that the condensation moisture may run out readily.

Let every one who reads this article do his own thinking, and act on St. Paul's advice, "Prove everything, and hold fast to that which is good."

LATER.—Since writing the above report the following is added, which may be of interest in connection with the subject:

On April 22 it was observed that the bees were working very strong bringing in pollen and honey. It was evident if they continued they would fill their hives of 16 frames in three or four days. In order to prevent this it was thought best to put on supers. Some of the strongest colonies were that evening unpacked sufficiently to get supers on, containing 24 one-pound sections each. The supers were covered with a cloth, an empty super put on, and the winter packing returned.

To-day, April 28, the packing was removed for inspection, and the first hive showed the eight outside sections all filled ready for capping; the others had some honey stored in the supers. The fruit-trees will be in bloom the first week in May. If the weather continues favorable we may expect from 10 to 30 pounds of surplus honey per colony. To what cause shall we attribute the flourishing condition of our bees? To the long and severe winter and poor stores? Or to the superior excellence of the Notre Dame hive for comfortable wintering, and also to an early honey-flow from maples, poplars, and other early-blooming trees, and to the fact that there was a sufficiently large force of bees in each hive to bring it home?

May 6. The apple-trees were in full bloom on May 3, at which time we had rain and some cool weather, but the bees did fairly well. The packing has been removed, and some of the hives have been put on the scales, for the purpose of approximating the amount of honey stored from the middle of April till May 6.

The first colony weighed 146 pounds; this colony weighed 80 pounds when put into winter quarters. A considerable portion of this must have been consumed during the time elapsed since last October, especially in rearing so much brood. This colony has 16 full-depth frames, and a super of 24 one-pound sections nicely capped. It is evident that this colony needs eight more full-depth frames so that the queen may have more brood-room, and the workers more space to store honey. It does seem early in the season to have colonies occupying 24 frames with 24 finished sections, but such is the case.

The next colony weighed was one formed by uniting two nuclei last September. This colony tipped the scales at 104 pounds; weight of the same hive last fall being 76 pounds.

The next one was the little swarm that issued from a glass observation hive about the first of last September, which has been mentioned above. This colony weighed 72 pounds, and is in excellent condition.

The last one weighed 148 pounds, the weight of which was 76 pounds last fall; 76 pounds less 35 pounds (the weight of the hive) leaves the net weight of bees and stores. It is quite possible that the greater part of their stores had been consumed before April 15.

St. Joseph Co., Ind.

The Making of Nuclei—Questions Answered.

BY G. M. DOOLITTLE.

ON page 138, Dr. Miller is asked this question: "I intend to increase my number of colonies the coming season by dividing. My plan of doing it is this: I have 14 old colonies, and want to increase them to 28 in all. So I thought I would take 14 of my new hives in which I want to hive the new swarms, and make a nucleus in each by putting a frame of brood and eggs, and one of honey in each hive, and then contract the inside of the hive with a division-board so as to keep the bees, which I intend to put into the hive confined to the side of the two frames. How many bees will I have to put into a hive? Will a pint do? And will these bees rear a queen from the eggs given them? Do you think a nucleus formed in this way will be all right? Would it be safe from robber bees?"

Now, as I intimated in a late article, I had expected to take the good Doctor to task for the way he answered that question, asking him a lot of questions regarding his answers to it, so as to draw him out further, but upon a later

reflection I have concluded to answer the same lot of questions myself, and then the readers of the American Bee Journal, as well as the Doctor, can see how we agree in the matter.

But before beginning at the general answering there is one item which I think should be noticed in the matter, which the Doctor never touched upon at all. The questioner says: "I thought I would take 14 new hives in which I want to *hive* the new swarms" (italics mine), which would show that after his nuclei are formed later on he intends to place the swarms, which may issue, into these same hives having nuclei in them, for as soon as his 14 new hives are occupied with nuclei he will have 28 hives with bees in them, and that is the number he says he wants. Consequently, if he has any new swarms at all they must be hived in with those nuclei, or he must procure more hives, in which latter case he would have more than the desired 28 in the fall.

I know that he speaks of dividing, in his first sentence, but knowing the nature of bees I know that unless he takes more than the one frame of honey and brood from each colony, as he proposes, he *will* have swarms to hive, and as he speaks of wanting "to hive the new swarms," I take it for granted that he expects the new swarms, and is calculating to hive them in with the nuclei. But how he is to do this is something the Doctor failed to tell us, intentionally or otherwise. There is only one way which I know of without having many bees killed, and making a general "muss" of it all around; and that way is to have all the queens with clipped wings, those in the nuclei after they begin to lay, as well as those in the full colonies; then when a swarm issues allow the queen to run into a cage, stopping her in. Next, carry the parent colony to the stand of the nucleus you wish the swarm to go into, setting the nucleus off and the parent colony in the place of it, immediately letting the queen out of the cage and allowing her to run in her old home. Now set the nucleus on the stand previously occupied by the old colony, and as expeditiously as possible, fill the hive with frames filled with comb foundation or empty comb.

By this time the swarm will have begun to return, and as quick as it does so, shake the bees and queen off their two combs down in front of the hive from a foot to 18 inches away from the entrance, when all will run in together without any quarreling, providing you smoked the nucleus on first removing it from its stand so its bees have filled themselves with honey. If you do not take these precautions the bees in the nucleus would kill the bees from the swarm as fast as they came back, in nine cases out of ten. The next day the nucleus and new swarm combined should be boxed, and the hive of the parent colony opened, and if the queen-cells are not already destroyed they should now be cut off, when, as a rule, swarming will be over with those two hives for the season, if plenty of section-room is provided for the colony having the old queen.

Now to answering the questions propounded: After telling us how he proposes to fix his hive with one frame of brood and one of honey he asks, "How many bees will I have to put into a hive? Will a pint do?" Well, that depends: If four quarts of bees are taken from any colony of the 14 our questioner says he has, and said 14 colonies are all in the same apiary where he is forming his nuclei, as it will be reasonable to infer, said four quarts will not be enough to make a decent nucleus of those two frames, providing *no precautions* are taken to make that four quarts of bees stay in that hive, for all but the very youngest fuzzy ones will go back home, and the fuzzy fellows run out in the grass and all about the outside of the hive where they will perish.

During my nearly 30 years of experience of forming nuclei with bees taken from a colony having a queen and putting them on a frame or two of brood and honey, it has been a great mystery to me how nearly every one will get back to the old hive, altho apparently half of those carried to the nucleus have never flown from the old hive before. But such is the fact, and it is useless to take bees from their mother and put them into a hive having combs of brood only expecting them to stay, unless they are fastened to the hive, or some precaution taken to make them stay "where put." But if you can go to your out-apiary, or to some neighboring bee-keeper, and get a quart of bees in a nucleus-box, such as I have described in previous issues of the American Bee Journal, and at the expiration of 24 hours put them on those two combs—one of brood and one of honey—you will have a good nucleus, and even if you so take bees from the same apiary in such a box, and keep them in the box 48 hours instead of the 24, feeding them so

they will have all the food they need, they will stay when put in the hive nearly as well as those from the out-apiary, but not quite, unless you give them a queen of some kind, virgin or otherwise, after they have been in the box from 8 to 12 hours.

And now allow me to disagree with the Doctor a little. He takes special pains to tell the questioner that if the bees do rear a queen from the eggs given, she will be "a very poor affair." Well, as I said before, without any precaution toward making the bees stay on that frame of brood, they would all leave, and if *so no* queen would be reared at all—a *poor affair* or otherwise; but where bees are taken from an out-apiary and kept in a nucleus-box without any queen for 24 hours, at the expiration of which a quart of bees is turned loose on two frames fixt as the questioner proposes, they will rear *just as good* queens as by any of the plans used which deprive the colony of its *queen* while the cells are being built, as I have proven time and time again; for, while in the nucleus-box they do "so long" for a queen that nearly all of them will prepare royal jelly, and when they have access to brood they will just "flood" the young larva chosen for a queen with it nearly, if not quite, equal to those being reared in a colony preparing to cast a swarm. And a quart of bees on the two frames will keep up the necessary heat to fully perfect those queens, where treated as I have given, fully as good as will a strong colony whose queen has been taken from them that they may rear queens.

While I *do not* recommend this way of rearing queens, if the doubting ones will try it they will become convinced that a quart of bees so treated will rear queens as good as any known a score of years ago, outside of those reared by natural swarming. And if this be so, then the question, "Do you think a nucleus formed in this way will be all right?" would be answered in the affirmative, and the robbing part the same.

The Use of Barrels as Honey-Packages.

BY C. P. DADANT.

IN a recent number of the American Bee Journal I see an editorial criticising the use of barrels as honey-packages. I will readily agree that tin makes a much more convenient receptacle, yet barrels have served us so long, especially to keep honey for several years, that I cannot help saying a word in their favor. We have, many times in the past, kept honey as long as three and four years in barrels without any trouble.

The important thing is to have good, tight barrels, sound and well dried. The great mistake many bee-keepers make when putting their honey in barrels is to treat them as if intended for wine or vinegar, or other wood-soaking liquid. A barrel which needs to be soaked in order not to leak, is not safe for honey. Only the very best hardwood barrels should be used for honey, and among these, those that have been treated to a coat of glue, as for coal-oil or alcohol, are the safest. These are entirely impermeable, and unless they have been soaked and again dried they will not leak. If they have remained in a dry place when not in use, all that needs to be done is to tighten the hoops on them just before using them, and keep them as before—in a dry place. We have used some barrels over and over again for 10 or 15 years without any loss.

As to taking the barrel apart to take out the honey, it is an easy job, and does not injure the barrel in the least if properly done. When we speak of barrels, we mean iron-bound barrels, for wooden hoops are unsatisfactory, always. To open a barrel of granulated honey all you need is a strong gimlet, a hoop-chase and a hammer or mallet. The barrel is set on end, the head is thoroly cleansed, and the gimlet screwed into the center of it. Then a couple of marks are made on the edge of the head to correspond with similar marks on the chime, so the head may be replaced in the same position as first found, after the barrel has been emptied. The hoops are then chased off, the staves spread a little, and the head is lifted off by the help of the gimlet. The honey may then be scooped out with a ladle, a scoop, a shovel, or even a spade, according to its density. After it has been entirely emptied, the head is replaced in exactly the position it occupied. A barrel treated in this way may be used over and over again without risk. This is not theory, but a practical fact, and the first thing I teach a new clerk who is expected to handle honey and put it up in different packages is how to remove a barrel head properly.

It is true that if we use the 60-pound cans we are saved

some trouble, but I do not believe I would trade good barrels for those 60-pound cans when harvesting honey which may have to be put into small receptacles, according to the customers' wishes. For instance, if we have a crop of 20,000 pounds of honey, and put it all in 60-pound cans, we may have orders for some 10-pound or 5-pound, or even smaller cans. You will ask, Why not put it up in different sizes? We have tried it, but this has to be done during the harvest, when we are busy, and then we do not know how much should be put up of each different size of packages. If it is all in 60-pound cans, when we take it out, to put, say 3,000 pounds in small sizes, we have 50 of those cans to empty. It is a great trouble to wash them, and it is not advisable to leave them sticky with honey for a season. If you wash them, they will not dry inside and will rust. If your honey is in large barrels the putting up of the 3,000 pounds will use up the honey of only about six barrels. These are easily emptied, easily cleansed, and ready for another crop without fear of rust or bad taste.

The demand for honey in 60-pound cans is on the increase, and I am glad of it. I should very much like to sell all the honey we produce in that shape, but we must cater to the trade, and I do not think that we will ever cease retailing out our goods in all sizes of packages, from 500 pounds to a single pound. We expect to use tin cans mainly, but we will always prefer barrels from which to put up different sizes according to orders.

One word of warning: It is unsafe to melt granulated honey and return it to the barrel while it is hot. Honey has such wonderful hygrometric properties that the hot honey will absorb any moisture that may exist in the wood and actually shrink it till it leaks. This does not happen with cold honey. We were caught at this twice before we understood what was the cause of the trouble. So if you have to melt honey do not put it back into the barrel before it is cold. It is always best to use a good, strong can—an extractor can is very good—as it may be used till the honey has all been drawn off. If large tin cans with open tops were not so inconvenient, they would make excellent packages to keep honey till the apiarist is ready to put it up for retailing.

I spoke of barrels glued for coal-oil or alcohol; I meant barrels that have not been in use. A barrel that has contained alcohol is safe for honey, but a barrel that has contained coal-oil is fit for nothing but coal-oil afterwards.

"EXPERIENCED NOVICE" A MISTAKE.

I like Cogitator's friendly criticisms, which are always very much to the point, and pleasantly given, but I cannot pass his last mention of the new phrase coined by myself, as it would appear on page 164—"experienced novice." By referring to the quotation on the page mentioned, the reader will readily perceive that I meant "inexperienced novice;" the mistake was made either by my fault or by a typographical error. Altho I do not have the infallible correctness which belongs only to erudite writers like R. L. Taylor, I much prefer being guilty of the use of synonyms than contradictory expressions. Hancock Co., Ill.

A Chatty Letter on Various Topics.

BY W. A. PRVAL.

THE WEATHER AND QUEEN-REARING.—The weather has been so fine for the past few weeks, and the days seem so long, that I spend very little time within doors. I am glad that I am able to be in the open air so much, tho I like to spend several hours each day in reading or writing. Lately I have been giving what spare time I can command to my bees. I am in hopes that I will be able to attend to the 40 odd colonies I have in such a way that I will secure a good crop of honey. Then I want to rear a lot of queens. I have found queen-rearing a very fascinating occupation. I don't know anything I like better. I have been reading up all the literature bearing upon the subject I could get hold of. I have been very much taken up with "Thirty Years Among the Bees." I think it is about the most interestingly written book on bees published in this country. The title, tho, is badly chosen; it should be changed in future editions. Then it should be re-written and published in nice book form and bound in cloth. I believe that if a book is worth printing it should be worthy of a decent cover. Of course, cheap editions could be issued for those who may choose them in less pretentious bindings. My edition is in pamphlet form. It is too much of a bee-classic to send out that way. I have read

"Scientific Queen-Rearing," but I do not like the plan in it nearly so well as I do those in the other book. Then, the latter gives the reader so many choices of ways that he can't go wrong, if he has had any previous knowledge of the business; and he is so honest in his expressions that it seems to me that one can't help but admire the man.

We have had no rain since the middle of April to speak of; there has been none this month, tho the weather has been threatening showers the past couple of days. Since I started this letter it has begun to rain some, and I should not wonder but we may get enough to lay the dust. While a good rain would be a benefit to the bee-pasturage, still, it would do great damage to the hay crop, much of which is now cut, and to the cherry crop, the earlier varieties of which are ripe. This fruit is much earlier than usual. Our black Tartarians are seldom ripe before the end of the first week in June. This year they are now ready to harvest. Cherries and most other fruit is not going to be a heavy crop in California this season, yet the fruit will be of large size and fine flavor. The trees are making a fine growth, which may indicate that there will be a heavy crop next year, provided there is not a dry season. The grain and hay crop in this portion of the State will be heavy; it will be above the average. In the lower part of the State I have been told by those who have been there recently, there will be no crops to speak of. Grass only five inches high is being cut for hay; here it is three and four feet high, and in some places more. I notice that Prof. Cook, in the last American Bee Journal, says that they have had but 7 inches of rain in his section; here we have had 23. I believe.

MR. PENDER AND THE UNIVERSITY.—When Mr. W. S. Pender was with me a week ago Sunday, I drove him thru the State University grounds, and showed him the several varieties of eucalypti we have introduced here. All the varieties grown in California are not to be seen in these grounds; neither was I able to show the gentleman all that are scattered over the place. I showed him some that are in other places hereabouts. I find that our names do not agree with many he calls by the same name. There is nothing like knowing the botanical name of a plant.

Mr. Pender was quite an observer of our styles of architecture; he said that we build very pretty residences. He wondered why the University did not have one or two large buildings rather than so many of various sizes. I told him that we were to have even more, and that some of the very fine and handsome buildings he saw were to be torn down along with all the smaller ones, and a grand system of building inaugurated, the plans of which are being prepared by the best architects in the world (there being an open competition and large premiums being held out for the best plans), and when everything is in readiness work will be begun. The plan is to make our State University the grandest in the world. The site is the finest possible, being about 200 feet above the bay, and opposite the Golden Gate. Our deaf, dumb and blind asylums, at Berkeley, have the name of being the finest of the kind anywhere, tho I hardly think the buildings are the best.

Quite a heavy shower fell while I was writing this page; it may rain all night. (LATER.—It did in showers, and neither did good nor harm—'twas too light.)

The indications are that honey is not going to be plentiful; the flowers do not yield much nectar. Perhaps later the flow may be better.

EXIT ADULTERATED HONEY.—To-day I called upon the grocer in Oakland where I deal, and where I sold some honey early this month, with the purpose of telling him that I was prepared to sell him some of this year's honey—extracted and comb—as I had commenced to harvest it. I was more than pleased to find out that my prospect of supplying the home market with extracted honey had increased very encouragingly recently. It came about in this way:

The city of Oakland has a health department that is up with the times; it has its health officer, sanitary inspector, food inspector, chemist, etc. It has a well equipped laboratory. Well, my grocer told me that the food inspector had called upon him a few days ago and asked to see what kinds of honey he was selling. He was shown some put up in glass jars or bottles—a piece of comb honey surrounded with what purported to be extracted honey. The markets here are flooded with honey put up in this shape, most of which bear the label of some one of the "syrup companies" of San Francisco. This particular sort that the grocer brought forth did not bear any label; it was a fair brand of the usual "honey" that has been so sold in the markets about the bay, and I suppose on the coast for many years.

But this sort of "honey" is getting its death blow. The inspector told the grocer *not to sell any more of the stuff as it is not fit for food.*

The grocer is an honorable young man, and will obey the arm of the law. I presume I can supply him with all the honey he may sell, and it seems that his store uses a good deal. I have been selling him some in bulk; he has some customers that like my honey better than the Southern California article, tho the former is usually darker than the latter. He says the folks at his home prefer my honey to anything they ever tasted in the honey line previously.

I believe the California pure food law is doing much good for the producers of wholesome foods. I notice that the labels of lots of things that I look upon as spurious articles of food now bear labels stating just what they are. It was a common thing here to see all kinds of oils intended for salad oil to bear the words "Pure Olive Oil." Now we see "Salad Oil," with the further information that it is obtained from cotton-seed. This is but a single instance of many others. Californians are very proud of their olive oil; like our honey, there is nothing else as good anywhere on the face of the globe (hic). Nuf said. Hurrah for *pure honey!*
Alameda Co., Calif., May 23.

Summer Work in the Apiary -- Seasonable Hints.

BY E. A. SNELL.

WITH the opening of the summer season and the opening of white clover bloom the most important season for the apiarist is at hand. It is a season full of interest and anticipations, and hopes usually run high. The main honey-producing season comes within the next few weeks, which time brings the bread and butter for family use for the year to a large extent with many, if a good crop of honey be secured. The results depend quite a good deal upon the skill and management of the bee-keeper. A good deal of work must be done if the best results are to be gained.

A good supply of hives in which to put new swarms should be all ready, and should be in a shady part of the bee-yard, so the hives may be reasonably cool when the swarms are put into them, for if the hives are hot, as will be the case when standing in the hot sun, the swarms are much more inclined to leave for parts unknown. The newly-hived swarms should be shaded for the same reason, and also better work will be done in the supers when they are put on if the extreme heat be avoided so far as may be.

The supers in full supply for a good season should now be ready. A foundation guide, or full sheets, should be in every brood-frame and honey-box. Any partially drawn combs should be used in the first frames or honey-boxes, as such are quite an inducement to the early entering of supers by the bees and work therein. These, when used, I prefer in the central part of the supers, and about three in each row of boxes when running for comb honey.

All hives and supers should be sweet and clean before using. Musty and filthy hives should not be used to put in new swarms, for such are often deserted, and I can see no economy in using such. Clean, new and good hives are cheap, and if kept well painted and properly cared for will last a lifetime. All utensils used in the apiary should be in order, and a place for each so that the apiarist may know just where to find them when needed, that no valuable time be lost in hunting them up.

The bee-yard, if in grass, should be kept mown down with a lawn-mower, and everything kept neatly, which is both pleasant and profitable, for more and better work can be done with such surroundings.

Supers should be placed on all colonies strong enough to begin the storing of surplus on time, so there will be no loss in the honey crop. Extra room should be given for surplus as needed. Experience will have to be the guide in this direction largely as to when this shall be done. The extent and length of the honey-flow must be considered in determining to how great an extent supers should be added.

As the white honey harvest nears its close the surplus department should be diminished in securing comb honey in order to get the greatest possible number of completed combs. At this time if too much room is allowed many boxes will be partially filled, and a less number completed. It is desirable to get the early honey as much by itself and as much of it as we can, and this can only be done by doing as above directed.

All newly-hived swarms strong in numbers should be given a super in about three days after being hived, and if

surplus cases are at hand having a few drawn or partially-drawn combs these should be given them, for it is very important that an early start be secured in the boxes—first, to secure more honey, and, second, to avoid the crowding of the brood-chamber with honey, and the risk of the bees getting the swarming impulse and giving no surplus, which would be the case if swarming occurred. The giving of more surplus-room than one case to new colonies should be decided by the honey-flow as indicated heretofore.

At the close of the white honey harvest all honey-boxes should be taken off and stored in the honey-room, which should be bee-proof. During the honey-flow all boxes should be removed as soon as the outside combs in the surplus cases are capt over. During a scarcity of honey, such as we have after clover and basswood, bees are much inclined to rob, and in removing or handling honey it should be exposed to the least possible extent. We find at such a time bee-escapes are very useful, for with them a large amount of honey may be taken from the hives and stored in the honey-room without any excitement being caused among the bees, or inclination to rob, which is very gratifying.

The honey-room should be a warm one, and well ventilated, so the honey may improve in quality by becoming thicker, which heat alone can do, and then best with circulation.

Queenless colonies, if any exist, would better be united with nuclei or light swarms or colonies, and the honey stored so robbers cannot get to it, for bees are on the alert to find stores at all times and in all ways. During a light honey-flow, such as we sometimes have late in July or August, and not good enough for work in boxes, some honey will be stored by strong colonies in complete combs, such as we extract from, and all strong colonies should be given such if on hand, and some more honey will thus be secured, which is some help, and may add quite a considerable to one's income with a large apiary, and in the same proportion with fewer bees. Get ready for a fall honey-flow.
Carroll Co., Ill., May 22.

QUESTIONS AND ANSWERS.

DR. C. C. MILLER.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Kingbirds and Bees.

What birds are bad on bees? I have but one colony of bees, and lots of kingbirds, catbirds, thrushes, etc., and do not want to kill any unless necessary. NEBRASKA.

ANSWER.—It isn't very likely that any birds do much damage to your bees unless it be the kingbirds. Sometimes they are troublesome, and sometimes not.

Caging the Queen.

I read very much about "caging the queen," which is a subject that I desire information upon. How is it done? I am in my second season of apiculture, and have never yet seen a queen, altho I have made diligent search and cut out queen-cells every eight days to prevent swarming. This last information I gained thru a friend who lives some distance away, thru correspondence. I have five colonies, and am greatly interested in bees and desire to enlarge, as I become conversant in apiculture, as I find it quite a woman's vocation. I am delightfully situated in the midst of 3,000 or 4,000 fruit-trees, desirable to bees. Is the enclosed cage what I need for caging queens? How is it used? OREGON.

ANSWER.—The cage of which you send a picture is all right, and indeed any kind of a cage will do that allows the bees to communicate freely with the queen thru its walls. If the object is simply to keep a queen caged in a hive, the

simpler the cage the better. You can take a piece of wire-cloth about four inches square, wrap it around a stick one inch wide and 3/4 thick, and four or five inches long. At one end tie some fine wire around to hold it together. Now slide the other end off the stick till about 3/4 of an inch projects, and bend or fold down the wire-cloth upon the end of the stick. Your cage is now complete. When you desire to use it, draw out the stick, let the queen run in, and push the stick in perhaps an inch. You may take the queen in your fingers and put her in the cage, or, if you are somewhat patient you may set the cage over the queen and let her run in of her own accord.

Crimson Clover—Italian Bees.

1. Will crimson clover sown in the spring, bloom before or in the fall of the same year that it is sown?
2. How is it for feed for all kinds of stock?
3. Would it pay me to get pure Italians, with another bee-keeper within a little over half a mile away keeping black or mixt bees all the time? He won't get pure stock.
4. Of all the bees, which do you think are the best for Kansas? KANSAS.

ANSWERS.—1. I sowed some in the spring, and some of it bloomed that same year, but the larger part bloomed early the next summer. It may not act in all places alike.

2. Fine.
3. You would stand no chance of keeping pure Italians with blacks only half a mile away, and yet it might pay you well to try to keep them. The hybrids would most likely be nearly as good workers as pure Italians, and occasionally introducing fresh Italian blood would keep up vigor.
4. Very likely nothing better than Italians.

Giving Swarms Combs or Foundation—Dividing to Prevent After-Swarms.

1. I have 16 colonies of bees in 8-frame Langstroth-Simplicity hives, running for comb honey. I have 16 more of the same kind of hives filled with good, straight worker-comb. Would you advise giving the new swarms full hives of comb? Or will the bees fill it with honey, leaving no place for the queen to lay? Which will be the better, the combs or foundation?
2. What is the best method for dividing, so as to prevent all after-swarms? WISCONSIN.

ANSWERS.—1. I should prefer the comb to foundation, but it may be well to give only half the combs at first, giving the rest 10 or 12 days later. For if all are given at first the bees would store in them rather than in sections.

2. One way is to take all but one or two frames of brood from a colony, leaving it all its bees, cutting out all queen-cells, and giving plenty of surplus room. Let the frame or two that you leave contain the youngest brood in the hive. The brood you take away may be put in another hive, brood from some other colony, if convenient, being added to fill out the hive, and this may be put on the stand of another colony which is removed to a new place. Care must be taken that all the cells are cut from these combs, and a laying-queen from a nucleus is to be given and left caged for two days.

Blacks and Hybrids in Same Hive—Transferring.

1. Is the queen fertilized by more than one drone? If by only one, what is your reason for both black and hybrid Italian worker-bees in the same hive?
2. Is it a good plan to transfer bees from box-hives by this method? Place a hive containing either comb foundation or comb underneath the box that you wish to transfer the bees from, and drive the queen and some bees into the hive that is prepared, and then place a queen-excluder on top of the hive. Leave the box on top of the hive say 21 days, then remove it as the bees will be hatch out in that time. ILLINOIS.

ANSWERS. 1. The belief is that in general a queen mates with only one drone. That part of the progeny take after one parent in color, part after the other, and part after both, is nothing unusual. In a family of 10 children with a black-headed father and a red-headed mother, you would not think it strange that some of them should have red hair, some black, and some a compromise.

2. The plan might do very well, only you would find it

difficult to drive bees down-hill into an empty hive. You would find it easier to drive them up-hill. Turn the box-hive upside down, put the new hive over it and drive the bees up, or drive the bees up into some box convenient, then put the bees in the new hive. It will be well if you can put at least one frame of brood in the new hive before putting the excluder over, otherwise the queen may be slow about commencing to lay.

Hives and Honey-Extractors.

1. What kind of hive would you call mine, which has a gable cover, holds eight brood-frames, and has only place for one super of sections under its cover?
2. Taking all these points into consideration, would you call it a good hive for producing extracted honey? It has no movable bottom-board, which is one thing I do not like.
3. What hive having a movable bottom-board is also good for the production of extracted honey?
4. Which honey-extractor is the best for general use, in your consideration?
5. One of my neighbors has a honey-extractor for which he says that he paid \$10 when new. It holds four frames of honey, and has a spout or faucet below for letting the honey out. What is its name? IOWA.

- ANSWERS.—1. I don't know.
2. It may do very well, but one can judge very little from the description.
 3. Any hive such as the 10-frame dovetailed, but remember that the best hive will accomplish little if badly managed, and with intelligent management almost any hive will do well. The man is more than the hive.
 4. My knowledge of extractors from actual use is very limited, but I suppose almost any of the extractors now on the market are good, the Cowan, that you mention, among them.
 5. I don't know. There may be more than one 4-frame extractor with a spout.

Starting in Bee-Keeping.

I now find that the closely confined office practice (doctor), and chemical work of a specialist, does not agree with my health. I am always well in the open air. So the question comes to me as it probably came to you (in a somewhat similar way) years ago, "Shall I keep on and die young, trying to lay up money here, or shall I be content with a living in close contact with nature, and live to a good old age?"

I have the best berry location—blueberries, blackberries and raspberries—in a radius of 15 miles; thousands of apple-trees, maples and small fruits; plenty of golden-rod and a moderate amount of other small honey-plants; little or no basswood, and acres of mountain laurel. Is it poisonous? Do the bees gather from it? An old farmer two miles off has 16 colonies that he manages on the old natural swarming plan, and lets the bees take care of themselves. He got 30 pounds of comb honey per colony last season, and said nothing about poisonous honey from laurel. If there was any doubt I would not risk it.

Do you think in the present condition of the honey business that I could make a living at it? How would you advise me to begin? Would you advise me to run for comb or extracted honey at first?

I had thought of starting 25 colonies in a correctly built house-apiry, and putting my increase out-doors and wintering them there.

I have sufficient capital to enable me to do what is necessary in order to start favorably. I have a brother in California and could start there if it seemed best. — R. I.

ANSWERS. Perhaps no other sort of questions makes me feel more keenly my incompetency to advise than yours. So many things must be taken into account, and with regard to a good many of them one can hardly have any positive knowledge. The best I can do is to reply somewhat generally. To one who desires to live to a good old age, keeping close company with nature, bee-keeping presents strong attraction. I should perhaps put it that I would rather die young after living a good many years than to die an old man after living but few years and laying up money that I could not enjoy. But the financial part cannot be entirely ignored, and that's where the pinch comes.

As to location, the probability is that you have a good one, but if you have told the *whole* truth about it your loca-

tion is poor. You have mentioned early honey-plants which are valuable to build up on, but which can hardly yield surplus, and late plants which will help fill up for winter, but say nothing of anything likely to give you a profitable crop, except to mention that basswood is scarce. Very likely, however, white clover is not lacking, and it is possible there are other good honey-plants that you have not mentioned. Please don't understand that those early honey-plants are unimportant. They are exceedingly important, because by their means your colonies can build up strong for the main harvest from clover, and possibly from other plants.

There is probably no foundation whatever for fear of honey from laurel. Many a feast of honey I've had in boyhood upon honey gathered where mountain laurel abounds.

To make a living from bee-keeping alone would be possible if you can live very economically, or if you could have a specially favorable location. In most locations there is a possibility that the very first year might be one of entire failure, and in many places the failures occur two or more years in succession.

If it is a possible thing, it would be wise for you to begin right where you are on a small scale, still holding on to your present position, and after a year or so of experience with a small number of colonies (beginning with not more than 10) you would be much better able to decide whether it would be wise to adopt bee-keeping as a vocation. As an avocation for a professional man it is a delightful thing, and it is entirely in the range of possibilities that one may stand the strain of professional life with the burden of bee-keeping added better than without it.

Very likely your best plan would be to begin working for both comb and extracted honey; then you could drop one, or continue both.

Better let the house-apiary alone till you have had some experience.

Altho you might have a wider experience by working for a time in some other locality, the probability is that your better plan would be to work right where you expect to continue. Bee-keeping in one place may be quite different from that in some other place.

As a final word, I feel pretty safe in urging strongly that you do *not* make any very serious investment at first, and that you do not put yourself in position to depend entirely upon bee-keeping until you have felt your way carefully, so managing that at any time you can give up the bees without loss, until you have gained some knowledge that may guide you to a wise answer to your own question.

Light Wired-Foundation is announced as the latest new thing, in *Gleanings in Bee-Culture*. A step farther than was taken by Capt. Hetherington and the Van Densens is to be taken, that is, a means of fastening the strands of wire to top and bottom-bar, or to the end-bars.

Diagnosing Foul Brood with a Microscope is considered by Prof. Cook impracticable for the average bee-keeper. He says in *Gleanings in Bee-Culture*:

"A good microscope could be had for from 20 to 30 dollars—one that would bring out these germs; but the skill and dexterity required in manipulation and determination would make it of little use to the average bee-keeper."

Renewing Queens at Two Years of Age is earnestly advised against by Herr Spuehler. In many cases a queen will do excellent work when she is three or more years old, and if she is doing good work when two years old the new queen that takes her place may not prove a gain. So long as a queen does good work, let her alone, leaving to the bees the task of removing her.—*Deutsche Bienenzucht*.

Narrow Sections.—Editor Hutchinson, of the *Bee-Keepers' Review*, mentions using sections 1½ inches wide, evidently not plain sections but with the usual inset, for he used them without separators, and after using some 5,000 of them he likes them. He thinks there may be some advantage in having the combs built 1½ inches from center

to center, for that is about what the bees favor when left to their own sweet will; the thin combs are filled and sealed more quickly; the combs are built straight and uniform; the combs are usually well attached to the wood and not rounded down and narrowed as in wider sections; the attachment to the wood being about the same as with wider sections, while the lesser weight makes less danger of breaking out; and, not least, he finds such sections very salable.

Does Foul Brood Wear Out? Prof. Cook says in *Gleanings in Bee-Culture*:

"I do not think that foul brood is very apt to leave an apiary when once established. I have known several apiaries in California entirely ruined by it. I would not say, however, that bees might not recover from this trouble, tho I have always had my doubts. Some of the best bee-keepers in California have assured me that they have known it to be present, and afterward disappear."

Bees Changing Worker-Eggs to Drone-Eggs.—Editor Simmins says in *Bee-Chat* that he has frequently seen cases in which workers have changed worker-eggs so that they produced drones. But he has doubts as to the ability of workers to change drone-eggs so they will produce workers. But, Mr. Simmins, if finding drones in worker-cells is proof of the first change, is not finding workers in drone-cells (a thing which sometimes occurs) equally proof of the second change? But as yet we may be excused for being skeptical as to either change.

Introduction of Queens.—Here's the plan practiced by J. A. Holmberg, given in the *Canadian Bee Journal*:

"The old queen is caged and placed on the top of the frames for two or three hours. Then she is destroyed and the new queen is put in the same cage, which is placed in the same place over the frames. After an hour she is released, when she is accepted readily. The bees think she is their old queen, now having the odor of the old one gathered from the cage and her position over the bees. He says the plan is a good one in his practice."

Control of Queen-Fertilization is claimed to be secured by J. A. Holmberg, as reported in the *Canadian Bee Journal*:

"He practices Doolittle's plan in rearing queens. His nuclei are supported, not only with nursing-bees but with a good supply of drones. He removes the nucleus to his cellar where he leaves it well supplied with honey for about three days. He then, at 5:30 p.m., after all outside drones have returned to the hives, brings out his nucleus, when the virgin queen and drones will at once rush out for a flight after their long confinement. After their return the queen is examined and if she does not show evidence of having met the drone, the operation is repeated and she is given another chance at the same hour on the following day.

Getting Bees Started in Sections.—Editor Hutchinson says, in the *Bee-Keepers' Review*, that when the flow of honey starts suddenly with a rush there is no difficulty in getting bees to work in sections with no special inducement, but let the flow be light at first, gradually increasing, and the probability is that some colonies—many, if light Italians—will think of swarming rather than beginning work in sections. In such case, "nothing will so quickly and surely lure the bees into the sections as will nice empty combs." He says two or three sections containing drawn comb are enough to start the bees at work, but as he uses no separators, the bees make better work if the whole of the sections in the super contain combs. Some who use separators succeed nicely with a single bait comb.

Preventing After-Swarms. G. M. Doolittle gives his two favorite methods in *Gleanings*. If the swarm is to be left on the old stand, it is hived on combs or on frames filled with foundation in the old hive, the brood-combs all being put in a new hive on a new stand, if necessary some of the bees being brushed off so that barely enough bees are left to take care of the brood, the weather being considered. Next morning one of these central combs is lifted out and a virgin queen allowed to run on it. The bees at once destroy all queen-cells. If the swarm is put on a new stand, he listens for piping the evening of the 8th day, and if none is heard he does not listen again till the evening of the 13th day. If no piping is heard by the evening of the 17th day, no swarm need be expected. Next morning after piping is heard, every queen-cell is cut off, the bees being shaken off each comb so that no cell may be mist.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee \$1.00 per Annum.

EXECUTIVE COMMITTEE. Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

JUNE 15, 1899.

NO. 24

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Growth of the New York Honey Market.—Formerly there was a demand during only part of the year, now it is continuous. There is a growing demand for extracted honey from druggists and confectioners, and for making honey-cakes, of which the Jews consume large quantities, and much extracted buckwheat is exported for making gingerbread. These items are given by J. E. Crane in Gleanings, and the editor adds that brewers now use glucose instead of honey, but bakers use large quantities of honey because it is the only sweetener that will allow the baked goods to remain moist without the expensive addition of glycerine.

Spreading Anti-Adulteration Information.—Mr. F. A. Snell, of Carroll Co., Ill., sends us the following which should commend itself to every one of our readers:

EDITOR YORK: The investigation of foods adulterated, which was made in Chicago and reported on page 313, is an important one. I took that copy of the Bee Journal to the editor of our home paper, and called his attention to the article, and it was freely and gladly accepted and published in the June 1st issue, a copy of which I will send you. It is printed in full, and credit duly given.

Now I suggest that you call the attention of your readers to the importance of each one taking a copy of the "Old Reliable" to his editor and secure its insertion. This one thing, so easily done, will be the means of bringing this cursed adulteration business to the greater attention of

the people. By each reader doing as suggested, it will be read, and food adulteration be denounced by tens of thousands of our people who from the very horror of the bad work, will press the importance of legislation, and stringent laws may be secured soon in favor of honest industries, and the punishment of the guilty rascals the adulterators—who have done so much to undermine the health of our people, and rob the legitimate producer of pure food.

Let every bee-keeper now promptly do good missionary work along this line, and we may as a people reap the benefit in the near future. While conversing with others let us talk this matter up, and present it to our law-makers.

F. A. SNELL.

We think Mr. Snell has done well, not only in getting his home newspaper to reprint the article referred to, but also in making the suggestion that others "go and do likewise." What is needed is more agitation along the line indicated. Only those who are in sympathy with evil of any kind want to keep it hushed up. Let the light be turned on until dark deeds and deeds that seek the darkness are shown up in all their wickedness.

Strong laws are needed against food adulteration of all kinds, and the way to get such laws is for those in favor of them to agitate the subject until victory is won. "Keeping everlastingly at it brings success" is a good maxim. Keeping everlastingly after wrong-doers is bound to lessen the wrong-doing after awhile.

Honey for Fine Cakes, Confectionery, Etc.—It seems that not only is the use of honey for such purposes on the increase, but the quality of the goods has been much improved within the past few years. Editor Root, of Gleanings in Bee-Culture, sent to one of the leading establishments of the National Biscuit Co., for samples of goods in which honey takes the place of sugar, and in reply received with the samples a note which said in part:

"We are sending you five varieties of cakes, in the formula for which honey is the principal factor; besides, it gives variety in flavor different from any other sweetenings, and it makes goods much lighter and finer in appearance. The names of the goods are as follows: Honey-jumbles, iced honey-cakes, frosted creams, honey-bars, and honey-cakes plain. We are on the increase every year in the use of honey in the manufacture of cakes."

Perhaps the most valuable feature of cakes made with honey is their keeping quality. As a test, A. I. Root kept some honey-cakes two years, when they were found to be just as good as new. And we had some in our office for two or three years after the World's Fair, in 1893, that had been made several years before that great show, and they were just as good as ever. Age seemed to have no effect on them whatever, unless it was to improve them. Many baking concerns in this country use extracted honey by the carload; and some of them seem to prefer the darker grades of honey, on account of their generally stronger flavor.

Suggestions for the National Association.—So long as advice costs nothing perhaps it will not be objected to. In the following we think Mr. Moore has given some good suggestions or advice, which we would like to see acted upon by the officers of the United States Bee-Keepers' Association:

The United States Bee-Keepers' Association has been doing much good in the past, and will no doubt do much in the future to benefit bee-keepers. But there is one thing that might be changed to the end that the Association shall be better advertised than it has been in the past. Let us have a short report, or article, every month from the general manager or secretary, or both, on the work the Association has done for the preceding month, and the new plans that are being made for future work.

A yearly report may be all right for old members, and those who have put on the harness; but how about the other 300,000 bee-keepers that we are anxious to get into the fold?

The greatest business enterprises have been built up on broadcast advertising, and this is necessary for every business, both small and great.

I take it that all the bee-papers would publish free any remarks Mr. Secor and Dr. Mason chose to make on the progress and aims of the Association. Articles could be sent to one bee-periodical with the request that all the others copy.

If the officers of the Association did not wish to make all the contributions themselves, they could request some bee-keeper to write a paper for publication on some phase of the Association's work. Suppose prominent apiarists look up the number and form of mixtures and adulterations of honey in Indianapolis, New Orleans, San Francisco, New York, Cleveland, and other large cities, and report the same thru the papers for our information and instruction.

The first step toward curing any disorder is a perfect knowledge of the symptoms. This matter of adulteration and prevention of the same is being agitated by the people more than ever before; and we must dig up new ideas and new methods of work, or have the procession pass us.

HERMAN F. MOORE.

We hope that Messrs. Secor and Mason will consider the foregoing suggestions in the same friendly spirit in which we know they are given. People are not tumbling over each other these days to get into an organization that they know but little about. Inform them, and they will be ready to join, provided the information shows it to be worthy of their support. Let us keep the excellent objects and work of the United States Bee-Keepers' Association ever and always before the bee-keeping public.

Apis Dorsata Caught at Last.—Gleanings in Bee-Culture for June 1 contains a letter from Rev. W. E. Rambo, a missionary in India, who has found a colony of *Apis dorsata*. It was on a limb of a tree about 60 feet from the ground, and very difficult of approach. Seen thru a field-glass, Mr. Rambo reports the bees as very beautiful. He spent from 9:30 p.m. till 4:30 a.m. in the tree; smoked the bees, and secured half of them, but does not know whether he got the queen or not. The single comb was 30 inches by about 15 deep. The greater part of the comb dropt to the ground, and was made into jam, but enough was secured to fill nearly three Langstroth frames. Those who are anxious to secure *Apis dorsata* will watch with much interest to see what success Mr. Rambo may have in taming the big bee.

— Mr. O. O. POPPLETON, of Florida, we understand, expects to be at the Philadelphia convention. He's a man worth seeing. There are many others like him in beedom. And some of them also will be in Philadelphia when the bee-keepers "swarm" there in September. Better get ready to go. The convention begins Tuesday evening, Sept. 5.

PROF. E. A. GASTMAN, of Decatur, Ill., is, I think, the nestor of superintendents of city schools in this country. For 38 consecutive years he has been in the public schools of that city, and its superintendent ever since it had a superintendent. On a delightful visit at his home he told me he had never made much money out of bee-keeping (I think he never reacht 100 colonies, and his location is poor, but the delightful out-door work had kept him in condition for going on with his work when others were worn out. I think he's about 65 years young. [The Doctor might have said that, had it not been for the bees, he probably would not have been among us now. Years ago, if I make no mistake, he gave up a lucrative position, having a fat salary attach to it, on account of his health. He preferred a

smaller salary, God's pure air, and a longer lease of life. And he got them. The bee-keeping fraternity can rejoice that we have so many professional men in our ranks. We have our lawyers, doctors, members of Congress, and our senators, school-teachers, professors in colleges, many of whom have been driven to bee-keeping as a pleasant and profitable pastime. Such men in our ranks have done much to enrich our literature and exalt our calling. Is there any other rural pursuit that can show such an array of talent? —EDITOR.] From Dr. Miller's "Stray Straws" in Gleanings in Bee-Culture.

HON. J. M. HAMBURGH, the inspector of apiaries for San Diego Co., Calif., writing us June 1, reported as follows:

"FRIEND YORK:— It has been so miserably cold and disagreeable on the coast that I have not been able to get out inspecting, but am awaiting suitable weather. This I know sounds strange to come from this land of sunshine. Yes, and to cap the climax, last night and to-day we have had in the region of 1/2 inch of rainfall, which, in consideration of the hay and grain crop being nearly all cut and lying loose upon the ground, is more of a calamity than a benefit. Of course it will help out the bees, and the fruits will be benefited, but it is one of California's 'little jokers.'"

DR. MILLER has told on himself again (and this time also gets somebody else's "fingers in the pi"). Here's one of his "Stray Straws" in June 1st Gleanings in Bee-Culture:

"On my return from Illinois Sunday-school convention I sat with Editor York and his efficient helpers around his festive board, or, rather at one side of the board, for the board was up against the wall in the printing-office, and the noon-day lunch tasted all the better because the fair hands that prepared it had been setting type just before."

It's a wonder the Doctor didn't tell what he had for dinner that day. But it likely was so little that it failed to fill up any, and thus was not noticeable. If those "fair hands" ever get hold of the Doctor again, they'll make a good case of printer's pi out of him. He won't be so "festive" after that.

MR. HERMAN F. MOORE, secretary of the Chicago Bee-Keepers' Association, is rapidly becoming one of the greatest bee-cranks in this part of the country. He talks bees most of the time when awake, and we doubt not his wife could testify to his keeping up an almost constant buzz in his sleep. Mr. Moore was invited to address the students of the academy of Northwestern University, at Evanston, Ill., on the subject of "Bees and Flowers," Friday, May 19. Prof. H. F. Fisk, principal of the academy, in a letter sent to Mr. Moore afterward, had this to say in reference to the apiarian address:

"MY DEAR MR. MOORE: I desire to express my hearty appreciation of your interesting address to the school on last Friday. . . . I wish I could give you an honorarium that would suitably recognize the real value of the service rendered to our young people.

"Yours very truly, H. F. FISK."

Then the Evanston Index for May 20 contained the following notice of Mr. Moore's talk:

"An address on 'Bees and Flowers' was given by Herman F. Moore, secretary of the Chicago Bee-Keepers' Association, at the academy chapel exercises yesterday afternoon.

"For an hour Mr. Moore kept the 'preps' interested by the number of unsuspected phases of apiarian lore he presented. Queen-bees and their royal vagaries, the best methods of hiving swarms, the races of bees, the hexagonal forms of cells, the differences in flavor produced in honey from different flowers, poisonous honey, wild honey, were all successfully treated. From these subjects the lecturer past to the great establishments owned by some American bee-keepers, and phenomenal yields of honey.

"The address was ingenious, and showed special research."

Mr. Moore is an interesting speaker, and fully informed on his subject. He is a hard worker, and unless we miss our guess he will be heard from in a very effective manner very soon. Keep your ear close to the ground for awhile.

Hildreth & Segelken,

JOBBER AND COMMISSION MERCHANTS.....

HONEY, Beeswax, Maple Sugar and Syrup.

120-122 W. Broadway,
NEW YORK.

We desire to inform our friends and patrons that our firm has been re-organized and additional capital added. The business will be conducted under the firm name and style of

HILDRETH & SEGELKEN,

at the old stand, where we have had the pleasure of serving our friends for the past 11 years. Management and supervision will be the same and our business methods—those of square and honest dealings—will be practiced as heretofore.

We believe we have won the esteem and confidence of our shippers throughout the country, and that our dealings, as a rule, have been of the most pleasant nature.

Our additional capital will put us in position to increase our already large business still farther, if possible, and at the same time enable us to treat our shippers even more liberally than heretofore, in making advances, etc.

Records will show that we handle by far the bulk of all the honey sent to our market. We make honey the principal part of our business, are personally acquainted and have trade connections all over the country, which enable us to handle any amount of honey to better advantage than any other house.

Old shippers know us and will bear us out in what we have said. Those bee-keepers who do not know us and have had no dealings with us, we would cordially invite to correspond with us and make our acquaintance. We not only handle on commission but buy largely as well, from small lots to carloads, for spot cash.

We wish to call the attention of the Southern bee-keepers to the fact that our market never was in better condition than this season. Old stock is disposed of and the market is bare, with a good demand. New crop will find ready sale and at higher prices than have ruled for years past. We would advise them to send their honey, while there is a good demand at good prices, as later on conditions of the market may change.

We also handle MAPLE SUGAR AND SYRUP very extensively, and would be pleased to hear from those having any of these goods to offer.

In conclusion, we wish to extend our thanks to all of our shippers for their past favors, and trust to receive their kind consideration in the future.

21A4 Please mention the American Bee Journal.

Queen-Clipping Device Free....

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & COMPANY,
118 Michigan St., Chicago, Ill.

Italians, Blacks, and Black-Italians Swarming Without Capt Queen-Cells.

Query 92. It is generally admitted, I believe, that Italian bees will sometimes swarm without having capt queen-cells in the hive, and sometimes even without having queen-cells started.

1. In the light of your experience, are you prepared to affirm that black bees can be depended upon not to swarm without capt queen-cells?
2. Same question applied to black-Italian hybrids.—MINNESOTA.

- A. F. Brown—1 and 2. No.
Eugene Secor—1 and 2. No.
C. Davenport—1 and 2. No.
Chas. Dadant & Son—1 and 2. No.
J. A. Stone—1 and 2. I am not prepared to say.
Mrs. L. Harrison—1. Yes. 2. I think not.
Dr. J. P. H. Brown—1 and 2. I cannot affirm.
W. G. Larrabee—1 and 2. I do not think they can.
J. M. Hambaugh—1 and 2. I am not authority on this subject.
E. Whitecomb—1 and 2. I don't know; have had no experience.
E. S. Lovesy—1 and 2. I have had no experience to speak of with any kind of black bees; my bees are mostly the leather-colored by birds from 1/2 to 2/3 Italian, and the

Extracted Honey Wanted

As soon as you have any good, well-ripened Extracted Honey for sale, send us a small sample, stating quantity, price expected delivered in Chicago, and how put up. Prefer it in 60-pound tin cans. Expect to be able to place carload lots as well as smaller shipments of Extracted Honey. But don't ship us any until we order. Address,

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

GLEANINGS ONE YEAR, and one untested Italian Queen, for \$1.00 only. We begin mailing these Queens in June, and orders are filled in rotation, so the sooner your order comes, the earlier you will get the Queen.

GLEANINGS ONE YEAR, and No. 1 Repairing Outfit. Price of this combination only \$1.75. We can ship these outfits from Syracuse, N. Y., Mechanic Falls, Maine, Medina, O., or Des Moines, Iowa, so the freight will be low.

GLEANINGS ONE YEAR, and Mantel Clock, both for \$4.50. Can ship clocks from Cleveland or New York City.

Last of All

If you don't want any of these Clubbing Offers, send us 50 cents for GLEANINGS the remainder of the year.

The A. I. Root Company
MEDINA, OHIO.

main incentive to the swarming habit is heat and overcrowding. I remove the cause, and have no trouble in the matter.

E. France—1. No. 2. No; altho all bees will usually have capt queen-cells when they swarm.

O. O. Poppleton—1 and 2. No, to both questions; but I have never known an instance of either doing so.

R. L. Taylor—1. No, but I never knew them to do it. 2. I have had hybrids swarm without capt queen cells.

R. C. Aikin—1 and 2. I have not had blacks for 20 years or more, and we did not think of that point before that.

Prof. A. J. Cook—1. No, there will be cases. 2. The same as No. 1. All bees may behave so. It is exceptional even with Italians.

Dr. C. C. Miller—1 and 2. I wouldn't like to say so under oath. I think Italians seldom swarm without capt cells *when left to themselves.*

Mrs. J. M. Null—1. Yes. 2. Yes. But the abnormal swarming with Italians is very rare, and then is often superinduced by lack of ventilation.

G. M. Doolittle—1 and 2. I see little difference in bees regarding the matter. In times of excessive swarming, all varieties of bees fail to observe general rules.

D. W. Heise—1 and 2. I have never known black or black-Italian hybrid colonies in normal condition to do so. I would not affirm, however, that they could be depended upon not to do so.

Mrs. A. J. Barber—1 and 2. I have had but little experience with black bees, so I cannot say. The few I had were so unsatisfactory generally that I destroyed the queens and Italianized them.

J. E. Pond—1 and 2. I am prepared to affirm that both black and "black-Italian hybrids" have swarmed in my apiary, not only without "capt queen-cells," but without a rudiment of a queen-cell at all.

C. H. Dibbern—I have never known Italians or any other bees to swarm without having queen-cells, either capt or uncapt. I am not prepared to say, however, that they will not sometimes do so, but I think rarely.

P. H. Elwood—When any variety of bees swarm without capt cells it is usually because the heat has driven them out. When queen-cells have been broken out of a swarm the bees are liable to swarm without capt cells.

Dr. A. B. Mason—1. No, I never kept black bees. 2. They cannot be depended upon not to swarm without capt queen-cells. They will sometimes swarm without making *any* preparation in the way of starting queen-cells.

Emerson T. Abbott—1 and 2. I have never known a swarm under normal conditions without queen-cells being started. In the light of my experience there are very few things you can depend upon any kind of bees doing every time.

Adrian Getaz—1 and 2. I find but little difference between the different breeds. Such swarming generally occurs when the colonies are much overcrowded, or lack sufficient ventilation, and are often absconding cases, rather than normal swarming.

S. T. Pettit—1. I have never known any bees to swarm without first preparing queen-cells or cups with the necessary egg in each. I have never known pure black bees to swarm without leaving capt queen-cells. 2. I cannot tell what hybrids may do under severe treatment.

Rev. M. Mahin—1. I have known Italian bees to swarm without having queen-cells even started. I have not had any experience to speak of with black bees. 2. I think that crosses between the Italians and blacks will sometimes swarm without queen-cells. There are no *hybrid* bees.

G. W. Demaree—From long and careful observation along this line of swarming, I am led to the conclusion that all the varieties of bees with which I have had experi-

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

ence are likely to lose their heads under the influence of sudden prosperity, and do eccentric things; among which may be swarming before queen-cells are even started.

Good Honey-Year Expected.

I began the spring of 1898 with 85 colonies in two apiaries, and took off 4,400 pounds of surplus, about 75 being extracted. I packed 100 colonies for winter and lost 20; about half of them became queenless, which I united with others. Some of those I have left are weak, but are now doing well. I had two swarms yesterday. There was considerable loss in this vicinity the past winter and spring. The prospects are good for a honey-year. **B. W. PECK,** Ashtabula Co., Ohio, May 27.

Small Loss in Wintering.

I wintered my bees outside, and lost three colonies; the others are doing very well; especially the colony of Italians in an observatory hive is doing exceedingly well. I expect a fine swarm from them soon. I have now 30 colonies. **EDW. ROWLAND,** Hudson Co., N. J., May 23.

Half a Crop Expected.

My 72 colonies of bees came thru the winter with a loss of one. I extracted 224 gallons of honey last week. I don't expect more than half a crop this year. Two-thirds of the bees in this county are dead; cause, starvation. Our people keep their bees mostly in soap boxes and hollow-logs, and

rob from the top. This time their knives were too long. One man lost 110 colonies out of 135; another, 45 out of 65; still another, 20 out of 21; another, 50 from 90. Some lost all. My son lost 3 out of 50. My daughter lost 4 out of 45. Everything is dried up for want of rain. H. F. BAKER.
Liberty Co., Fla., May 22.

Bees in Good Condition.

Bees are in good condition, and conditions are favorable for a good season. There was considerable loss among old-style bee-keepers here the past winter.
S. W. SMILEY.
Lincoln Co., Mo., May 15.

Colonies Built Up Fast.

I lost two colonies out of 18 in winter, and three were queenless. One of the colonies was strong with bees, but was queenless.
Our white clover is nearly all winter-killed. The spring has been so wet and cold that the bees have not been able to do very much on fruit-bloom, but they seem to be building up pretty fast. I see there are some drones flying already. We like the American Bee Journal, and hope that all its readers will be like us—pay two years in advance.
R. CHINN.
Dixon Co., Neb., May 24.

Wintering Bees on Honey-Dew.

Bees in this section of West Virginia wintered only moderately well, and I have come to the conclusion that honey-dew was the cause, for the colonies nearly dwindled down to only a few bees thru the winter, but only three died out of 51, which I consider a light loss for wintering on the summer stands. One of them had 25 pounds of honey in easy reach. Nevertheless, as soon as the warm weather set in they reared brood as fast and lookt as healthy as in any other season. I feed sugar in the spring for a stimulant, and especially watch carefully for intervals when they get no honey, so as to keep brood-rearing going on. I also practice spreading brood, which I now am very successful with, while before, being inexperienced along that line, I lost several colonies for meddling with them.

I think it is a great help to put the colony in condition for honey gathering as early as possible, especially when the queens are not of the very best quality, which need pushing to do their demanded duty.

My bees are in fair condition now, as out of 10 colonies thru which I lookt to-day, 8 had partially completed queen-cells, which means swarms in the first week of June.
Success to the American Bee Journal.
W. C. KAUTZ.

Webster Co., W. Va., May 26.

Beginner's Experience—Coal Smoke

I purchast 4 good, strong colonies of bees from a neighbor bee-keeper last spring, and as I was inexperienced, the man I bought the bees of imparted his bee-knowledge very freely, which favor I certainly appreciated. Before I was thru caring for his bees (for he went away to Kansas, leaving his bees in my care), I had gained considerable knowledge about them. From my 4 colonies one swarm issued about the first of May, unexpectedly to me, which I lost, as they came out while I was away from home. After this I had no more swarms, for I watcht them very closely, and when they showed signs of swarming I would divide them by taking, say two frames of brood with all adhering bees from one hive, say No. 1, and placing in a new colony I aimed to form, then removing No. 1 to a new stand, and putting my new one on No. 1's old stand, to catch the field-bees from No. 1. Then to weaken other strong colonies, and give Mrs. Queen more room to deposit her many eggs, I removed from each strong colony from one to two frames well filled with brood, shaking off all bees, and also placing them in the new colony

Don't fail to mention the Bee Journal when writing advertisers.

just formed from No. 1, sometimes making my new colony almost as strong as any of the others, thereby discouraging swarming in many other colonies. I put in empty frames where I take out frames of brood in all the hives.

I increased to 8 last season, and got more honey than I expected, considering the dry weather.

My bees came thru the severe cold last winter better than I expected they would. I did not lose any wintered on the summer stands.

I have increased from 8 to 11 this spring, and have had no swarms so far. Bees are doing fairly well, yes, extra well, considering what they have gone thru in the past 6 or 8 months.

I was manipulating a very strong colony of bees in the bee-yard a few weeks since, and they got pretty badly worked up, so much so that they told me (by their actions) to "git," which I did, for my smoker had failed to smoke when I needed it. So on my way to the "chip-pile" (to recruit my smoke) I passed the coal-house, and thought I, "I wonder if coal-smoke would not quiet them?" So I dumped in a single handful of small lumps, and again made a charge upon them. But, alas! when I marched forward with a cloud of black smoke rising, they ran like cowards. Is coal smoke injurious to any part of the colony—I mean to the queen, bees, brood or honey? If not, try it once and see the result.

Wm. HITCHCOCK.

Lonoke Co., Ark., May 20.

Good Honey from Alabama.

I send a sample of extracted honey, taken May 22 from frames 3/4 capt. I want to know thru the American Bee Journal how it compares with your best grades in body and color. One of our best honey-plants (ti-ti) failed on account of the freeze in February.

L. W. McRAE.

Washington Co., Ala., May 23.

[The generous sample of honey came all right, and we find it quite equal in body to the best honey we are acquainted with, but think in color it is a shade darker. But it certainly is fine honey, and should suit any body who cares at all for "the real thing." EDITOR.]

Bees in Fine Condition.

I did not lose a single colony the past winter, on the summer stands. I use the Hill's device on top of the frames, and the super is filled with leaves; then I turn a bottomless box over the whole thing, with bee-space in front. I keep the snow from the entrance, and when there comes a warm day after a long cold spell, when some of the bees are flying, I give the hives of those that are not out a few good kicks which makes them all have a good flight; then they are in good condition for another cold spell. If the bees are sick from black honey, I turn the hive down to the sun, take the bottom-board off, and let the sun shine in the hive. This will make them all have a flight. Before night fix them all back in good shape. Several of my neighbors lost half of their bees. Black honey was the trouble. The prospect is fine for a crop of honey. The white clover is looking well, but we are having too much rain.

Samamon Co., Ill., May 31. C. V. MANN.

P. S.—Hold on a minute. Bees are swarming. I have them in their new house. It was a fine, large swarm. This is my first swarm for the season of 1899. C. V. M.

The Yellow Sweet Clover.

I do not think that the value of yellow sweet clover—*Mellilotus officinalis*—is known or appreciated as it should be. There is very little white clover to be seen in this locality, as it was destroyed by the severe freezing last winter, in the absence of snow, but the yellow sweet clover is in full bloom like a bank of gold.

It blooms fully a month before its rival—

Mellilotus alba—and is a great favorite with the bees; neither does it grow half so tall, nor so rank; the stalks are finer, and the bloom more abundant.

From my experience in saving the seed of these clovers, I think it heats easily. While at a seaside resort I noticed a few plants of this clover growing on the edge of a salt marsh. I made a little cotton sack, and every day I gathered the seed as it ripened. When at my rooms I kept it in a valise; none of the seed grew. If I had dried the seed in the sun it might. I made the same mistake while gathering the seed of the white sweet clover in Iowa, while there on a visit. Any one who fails to grow this clover should transplant a few plants, and if they grow, it will be established for all time. It appears to thrive best when beaten well into the soil, and wagon-wheels during a muddy time plant the seed along highways for miles. Some of the railroads have ascertained the fact that it is a good plant to keep their cuts from washing; and it would be good for the South to plant it on their gullied lands.

MRS. L. HARRISON.

Peoria Co., Ill., May 31.

Rolling in the Honey.

Bees in Tulare County are doing well. I have 48 new swarms so far, making 98 colonies in all. They are rolling in the honey now from alfalfa bloom. I believe this will be a good honey-year in this county.

Tulare Co., Cal., May 19. DAN CLUBE.

15Atf Please mention the Bee Journal.

CHAS. F. MUTH & SON.

I wish to announce to my friends and patrons that I have this day sold to C. H. W. WEBER, of Cincinnati, my Honey and Bee-Keepers' Supply business, known for the past 38 years as CHAS. F. MUTH & SON. Mr. Weber will continue to push the Langstroth hive and everything pertaining to same; besides, he has secured the agency for Mr. Root's goods, and will sell them at his prices. I beg the customers of the old house, to whom I wish to extend my thanks, to continue their patronage with Mr. Weber, by whom I am sure they will be accorded fair and honest treatment.

MRS. ANNIE MUTH Widow.
Cincinnati, Ohio, April 7, 1899. 15Atf

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, June 8.—Not any new comb on the market, and some of the amber and dark grades remain unsold. Extracted sells up on arrival—white at 70c; ambers, 69 1/2c, according to quality, flavor and package. Fancy white comb would bring 13c; off grades of white, 11 1/2c; ambers, 10 1/2c. Beeswax, 27c.

R. A. BURNETT & CO.

NEW YORK, June 9.—Demand good for extracted honey, all kinds, and same finds ready sale at the following prices: Fancy, 7 1/2c; choice, 6 1/2c; fair, 5 1/2c; common, 5 1/4c per gallon. Some demand for comb honey at from 11 1/2c for white, and 9 1/2c for amber. No more demand for dark. Beeswax dull at from 25 1/2c per pound, according to quality.

HILDRETH & SEGELKEN.

SAN FRANCISCO, May 31.—White comb, 10 1/2c; amber, 7 1/2c. Extracted, white, 7 1/2c; light amber, 6 1/2c. Beeswax, 26 1/2c.

Supplies and demand are both light. Small quantities of new crop extracted, light amber, have been placed to the retail trade at 6 1/2c. Old honey is still on market.

CLEVELAND, March 9.—Fancy white, 13 1/4c; No. 1 white, 12 1/4c; A No. 1 amber, 10 1/2c; No. 2 amber, 9 1/4c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.

A. B. WILLIAMS & CO.

BOSTON, May 17.—Fancy white, 12 1/2c; A No. 1, 11 1/2c; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7 1/2c; light amber, 6 1/2c. Beeswax, 27 1/2c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is liked at this season of the year.

BLAKE, SCOTT & LEE.

KANSAS CITY, May 15.—No. 1 white comb, 15c; fancy amber, 14c; No. 1 amber, 13 1/2c; fancy dark, 13c; No. 1 dark, 12c. White extracted, 6c; amber, 5 1/2c; dark, 4 1/2c. Beeswax, 25c.

C. C. CLEMONS & CO.

BUFFALO, May 5. The season for honey is about closed. Some extra fancy white would sell at 11 1/2c; some very poor selling at 6 1/2c, and dull. No more business in honey before the opening of the ensuing season.

BATTERSON & CO.

OMAHA, June 2.—A few little lots of new honey from Texas have made their appearance on the market. The stock was put up by inexperienced people and only sold at moderate prices. Extracted of fairly good flavor brought 5 1/2c. Comb honey put up in 6-gallon cans and filled with extracted sold at 6 1/2c. This is a most undesirable way of packing comb honey. Trade does not care for it.

PEYCKE BROS.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10 1/2c; dark and amber, 8 1/2c. Extracted in fair demand without change in price. Beeswax, 25 1/2c.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey.

M. H. HUNT.

WHEN YOU WANT QUEENS. Send us your order. We will fill it by RETURN MAIL, with the best of Italians, large yellow Queens, healthy and prolific, workers gentle and the best of honey-gatherers. The Novelty Pocket-Knife

(A heavier and stronger knife than the one we offered heretofore.)

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the Subscriber.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the Novelty is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the Novelties, your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be apprised of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00), and we will also send to each new name a copy of the Premium Edition of the book, BEES AND HONEY. We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

I ARISE

To say to the readers of the BEE JOURNAL that **DOOLITTLE...** has concluded to sell **QUEENS** in their season during 1899, at the following prices:

- 1 Untested Queen \$1.00
- 6 Untested Queens.. 4.50
- 12 Untested Queens 8.00
- 1 Tested Queen . . . 1.50
- 3 Tested Queens . . . 3.50
- 1 select-tested-queen 2.00
- 3 " " " Queens 4.00
- Select Tested Queen, previous season's rearing, 75¢ Extra Selected, for breeding, the very best, 55.00. About a pound of Bees in a 2-frame nucleus, with any Queen, \$2.00 extra.

Circular free, giving full particulars regarding each class of Queens. Address,

G. M. DOOLITTLE,

11A26t Borodino, Onondaga Co., N. Y.

22nd Year Dadant's Foundation. 22nd Year

Why does it sell so well?

Because it has always given better satisfaction than any other. Because in 22 years there have not been any complaints, but thousands of compliments.

We guarantee satisfaction.

What more can anybody do? **BEAUTY, PURITY, FIRMNESS, No SAGGING, No LOSS. PATENT WEED PROCESS SHEETING.**

Send name for our Catalog, Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

The following dealers handle our Foundation:

Why Not Just Double

The List of Subscribers to the Old American Bee Journal?

We really believe that if ALL the present readers of the American Bee Journal were so inclined, they could help to double its regular list of subscribers before August 1, 1899—or during the next 5 or 6 weeks. We do not find any fault with what our subscribers have done in the past toward increasing the list of Bee Journal readers—for they have done nobly—but why couldn't the doubling of the list be accomplished within the next month? We surely think it could be done, and in order that it may be easier for those who help in it, we will make a **SPECIAL NEW SUBSCRIPTION OFFER**, and also pay all who will aid in securing new subscribers. Here is the offer:

Six Months for 40 Cents to a New Subscriber....

Yes, we will send the American Bee Journal **EVERY WEEK** from July 1, 1899, to Jan. 1, 1900—20 numbers for only 40 cents, to a **NEW** subscriber. In addition to this we will send to the present regular subscribers, for the work of getting new 6-months' readers, their choice of the premiums mentioned below, but no premium will also be given to any new subscriber on these offers, under any circumstance:

For **Sending 1** New 40-cent Subscriber
 —Your choice of one of the following list:

- Poultry for Market.
- Our Poultry Doctor.
- Capons and Caponizing.
- Foul Brood—Kohnke and Cheshire.
- 10 copies York's Honey Almanac.

For **Sending 2** New 40-cent Subscribers
 —Your choice of one of the following list:

- Dr. Howard on Foul Brood.
- Monette Queen-Clipping Device.
- Bienen-Kultur (German) by T. G. Newman.
- Dr. Tinker's Bee-Keeping for Profit.
- Pierce's Winter Problem in Bee-Keeping.
- Bees and Honey (160 pages, paper) by Newman.
- 20 copies York's Honey Almanac.

For **Sending 3** New 40-cent Subscribers
 —Your choice of one of the following list:

- Bees and Honey (160 pages, cloth) by Newman.
- Bee-Keeping for Beginners, by Dr. J. P. H. Brown.
- Bienenzucht und Honiggewinnung (German) by J. F. Eggers.
- Advanced Bee-Culture, by W. Z. Hutchinson.
- 30 copies York's Honey Almanac.

For **Sending 5** New 40-cent Subscribers
 —Doolittle's Scientific Queen-Rearing.

For **Sending 6** New 40-cent Subscribers
 —Prof. Cook's Bee-Keeper's Guide.

NOW FOR A GRAND PUSH FOR NEW SUBSCRIBERS!

It seems to us that with the above low rate to new subscribers, and also the premiums offered, we should get such a landslide of new subscriptions as will make us sweat to care for them during the next few weeks without any help from the hot weather. WE are ready now to enter the new names and mail the premiums. Are YOU ready to go out and get them, and then send them in?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

CONTRIBUTED ARTICLES

Ants—An Interesting Nuisance—How to Get Rid of Them.

BY PROF. A. J. COOK.

I AM requested by a subscriber to the American Bee Journal to write an article on these little insects, which have been famous in prose and poetry all down the ages. It is not strange that the bee-keeper should wish to know more of the ants. Next to bees—and perhaps we do not need to make this exception—the ant certainly stands at the head of the insect world, as does man at the head of the Vertebrate branch.

Again, ants are quite like bees in the economy of their society. The bee-keeper is also interested in the fact that the ant is quick to discover honey-dew, and such insects as secrete it. The ant also becomes sometimes the enemy of the bee-keeper in that it enters the hive and causes no little disturbance. It is even reported that the ants sometimes destroy the queen-bee, tho I have never had satisfactory proof that such is positively true. While it may happen, I doubt if it is ever a common enough occurrence to cause alarm or even disturbance.

The ant, like the bees, many of the wasps and the white ants, which belong to a different order of insects, are truly social. They live in large colonies and work together, each for the good of all. They live for the most part in the ground, tho some of the boring ants live in the holes which they bore in trees. Sometimes they fairly tunnel the trees, cutting them so extensively that they are honey-combed. I have never seen trees bored by any insects more thoroly than by ants. Even the white ants of tropical regions do not their work more perfectly than do some of the true ants which we are now considering. In every formicary, which name is used to designate a colony, there may be found not only the queen, male and worker, but also soldier ants, which are the protectors of the colony.

The ant belongs to the family Formicidae, hence we understand why a colony is called a formicary. In the winter only worker ants, queens and soldiers are found in the nest. As with bees, when spring comes drones and young queens are reared. These, unlike the workers and soldiers have wings, and in spring or early summer fly forth, often in great numbers, to mate. The drones, or males, die at once after mating, as do the drone-bees, but the queen is taken possession of by workers, ready to emigrate from the old home and form a new one, is conducted into some subterranean retreat, and thus a new colony is formed. The first thing the workers do is to bite the queen ant's wings off, so she must perforce stay at home. We see then that the bee-keeper has a precedent set him by the ants in favor of clipping the queen's wing.

The food of ants is both insectivorous and vegetable. We often see them carrying insects to their nests, and as every one knows, seeds form quite a prominent part of their diet. Indeed, the agricultural ant of Texas, clears the ground, sows the seed, and raises its own grain. These ants also mound about the entrance to their tunnels on low ground, to keep out the water. In case water enters and their stores of grain are wet they carry it out to dry that it may not injure by fermentation. Thus we see that the ant even seems ahead of bees in its functional development.

Ants also make slaves of other ants, and some have carried this on so long and so generally that they have lost the power to care for themselves, except as they secure these slaves. Some ants bridge or tunnel streams, and it is authentically reported that in India, where some leaf-eating ants do great damage, they practice division of labor. They work by night, and some ants go up the trees, cut off the leaves, while other ants carry these latter to the nests.

In Colorado there is a strange development of some of the ants into storehouse forms. Each ant is little more than stomach and legs, and always attaches to the rock in its cave home, where it receives honey-dew brought in by the other ants, and so is a sort of honey-comb for storing this nectar. As the other ants want this honey they receive it from the storehouse ants, much as we see bees yielding

up honey to others of the colony. The Indians use these for desert, manipulating the ants much as we do grapes, as we use them for like purpose.

I stated before that ants often show us the presence of honey-dew, and so of plant or scale lice which produce it. Indeed, it is rare to see ants going up or down trees, bushes or other plants, where, upon examination, we will not find plant-lice or scale insects if we carefully look for them. It is probable that the insects secrete the honey-dew to attract the ants, bees and wasps, and thus protect the honey-dew-secreting insects from birds. The birds will not come near the plant-lice or scale insects when guarded by these bees, wasps, etc. The ants have learned so well the good office of plant-lice that they frequently keep the plant-lice in their homes, feeding and caring for them that they may receive this nectar which the plant-lice secrete. When disturbed, the ants will frequently carry out the plant-lice before they do their own brood.

I have stated above that the ants frequently enter the hives and greatly annoy the bees. Every bee-keeper has had many cases of such interference. In some sections of the country the hives are set high from the ground to prevent this intrusion of the ants. I have had reports from the Southern States that the ants occasionally destroy the queen-bee, which, as suggested above, may occasionally be true, but I think there may be some doubt about it.

Ants are often a serious annoyance on our lawns, and by getting into the house, where from their small size they are able to seek out almost every article of food. It is not difficult to prevent such intrusion. In case of disturbance on our lawns, if we search out the anthills we may easily destroy the ants by the use of bisulphide of carbon. By use of crowbar or other rod (wood or iron) we make a hole into the anthill, reaching to the bottom, which the softer ground enables us easily to find or determine. We now pour in a teacupful or so of bisulphide of carbon, cover quickly with clay, and compact this so as to prevent the poison from passing off. The liquid quickly vaporizes, and being held in the nest destroys all the ants that are in the tunnels. This should be done when the most of the ants are in the nest.

I have found the best substances to repel ants from the house to be corrosive sublimate and buhach, or insect powder. The corrosive sublimate may be brushed along the floor where the ants enter, or strings may be dipt into it—carpet-rags do well—and laid along where they will obstruct the ants' path. The ants seem so averse to this substance that they leave at once. Dusting with the buhach also clears them out, but the treatment may have to be repeated every week or two. We have been troubled not a little with ants in California, but have found the above methods very efficient in ridding our houses of this pest.

Los Angeles Co., Calif.

The Sting of the Honey-Bee and Its Use.

BY C. P. DADANT.

THE sting of the bee, as well as that of other hymenoptera, is practically a sharp double sword, well sheathed when in the body, and protruding beyond that sheath when in the act of stinging. Those two blades are barbed, and when once driven into the wound—which is done usually by an alternate motion of the two darts—are as difficult to extract as a fish-hook would be. When the bee stings, if it is left alone, and the sting has not been driven too deep, she will extract it out of the wound by turning it around and around, which probably twists the barbs and presses them against the blade, allowing its withdrawal.

The poison is a transparent liquid of great venomous power—more deadly than that of the rattle-snake, for the latter may be taken into the stomach with impunity, while that of the bee would cause sickness. Reaumur and Della Rocca both report it as burning the tongue almost like scalding water. A. I. Root compares its strength and taste to a compound of cayenne pepper, onion juice and horse-radish. So the only reason why the sting of the bee is not more dangerous is that the quantity of venom ejected is so very minute. In fact, the pain caused by the sting is greater or less according to the quantity of poison forced in. Were it not for this poison, the wound made by the sting would hardly be perceived. It is therefore of great importance that the sting of a bee be removed promptly, especially because it has a spasmodic action, even after it has been separated from the body of the bee, which continues forcing poison into the wound until it is nearly all ex-

hausted. But in taking it off great care must be exercised not to press it or pinch it, as the poison-pouch would thus be entirely emptied into the wound. It should be brushed off or scraped off without a second's delay. The smell of the poison is very noticeable, and reminds one of the smell of ants, for it is indeed very similar to formic acid. This pungent smell irritates the bees, and adds to their irascibility.

But if the sting of bees is a dangerous poison, it proves to have also medical properties, like most violent poisons. It is a well known fact that it has often cured rheumatism. At least numerous reports of such cures have been made at different times by bee-keepers thru the papers, and this is doubtlessly not without good foundation. But this is a "heroic remedy," and very few people will be willing to get stung experimentally for this purpose, unless they be as indifferent to stings as Reaumur, the great entomologist of the XVIIIth century, who relates in his book having caused a wasp to sting him at three different times in succession, just to see whether the wasp would be able to furnish as much venom at the last as at the first. He found, as might have been expected, that the last sting was not painful because the venom-sac had been emptied by the two previous punctures. He says that at a fourth trial he

EXPLANATORY.

Sting with Lancets drawn one side, cross-section of Sting, and a Lancet, much magnified.

could not succeed in inducing the insect to sting again. The poor wasp had evidently given it up for a bad job.

The queen-bees have a sting, but it is small, curved, and used only in fighting with rivals. A number of experimenters have reported being stung by queens, and in every instance the sting was said to cause but little pain. The poison-sac of the queen is like her sting—of secondary importance.

What is the necessity of so dangerous an "arm" as the bee possesses? Is it solely so she may be able to defend herself against us? This is not probable, and altho it is possible that without such a weapon the bees might long ago have been destroyed by man's rapacity, so as to disappear entirely from the earth, yet this weapon is necessary to them to protect them against many other enemies. There are a number of honey-eating insects that are both larger and stronger than the honey-bee, and some animals, like the bear, are so fond of honey that the fear of the stings alone can keep them away. But in their own hive the bees need a weapon. Were it not for that weapon, it is quite probable that those big, burly drones that are reared every spring with such care, and so mercilessly destroyed in the fall, would take advantage of their size to live on thru the winter at the expense of the workers, and with the great risk of starving them out.

If they are well armed for attack, our bees are also well fitted for defense. As many a combat takes place between inhabitants of different hives, owing to the greed and pilfering dispositions of many bees when the honey season is at hand, if one bee could readily pierce another with its

venomous sword, great mortality would ensue. Luckily Nature has dressed them in an armor—a coat of mail—the ordinary shell of most insects, made of a horny substance called "chitine." So it is only in the joints of this armor that the bee is vulnerable, hence the long fights between inhabitants of different hives, and the ease with which the robber often gets away.

Hancock Co., Ill.

Putting Up Extracted Honey in Glass Packages.

BY C. DAVENPORT.

SOME one has said in effect that it might be of benefit to others if we would describe our mistakes and failures, so I am going to mention how I lost about \$70 besides much time and work. Still, the matter could hardly be called a failure, for a most singular success was attained, but not just in the manner expected or desired.

When commencing to put extracted honey on the market the best style or kind of package was with me a matter of much perplexity, and after trying many and various kinds of packages, I finally decided that the Mason glass jars, in their various sizes were, all things considered, about the most satisfactory packages that could be obtained here for the retail grocery trade. The glass itself, barring accidents, lasts an indefinite length of time, and as the caps or covers are made of zinc they do not rust, and if they become discolored or old-looking there are a number of preparations by which they can be very quickly and easily cleaned so that they look as bright as when new. On this account these jars, after being emptied, represent, or are worth, about as much money as when new—something that can hardly be said in favor of any other retail package with which I am acquainted, and usually even the most thrifty of housewives will hardly object to the cost of the jars, owing to the almost universal use that is made of them by all classes for canning fruit.

But I found one great objection to their use, and this was that soon after they were filled the honey would ooze or run out enough around the rubber ring to keep the jar sticky. At first I thought the rubber rings I had must be defective, or of poor quality, but I found out, as undoubtedly every one else has who has used this style of package, that with no kind of rubber rings can honey be sealed so but what enough will escape to keep the package sticky, and this makes it, aside from being disagreeable to handle, very objectionable in other ways, for it catches and holds the dust and attracts flies and other insects, and on this account I found a number of grocers who, after a trial of them, refused to handle or have anything to do with them.

So I went to work and tried to make some kind of a band or ring that would hold honey, and the expense I have mentioned was for dies, material, traveling expenses, etc., during the time I was working at this.

I had a long talk with a man who bottles up tons of extracted honey each season; he uses corks and sealing-wax, and said a wide-mouth jar with a screw cap was preferable in many respects, but he had found the same difficulty I have described, and had tried rings or bands of different material, but without success. He said it was the action of the acid in honey that made rubber rings defective for sealing.

I did not say anything about the work I was doing in this line, for I expected to meet with success, obtain a patent, and soon be able to spend the winters in Florida, or even start a new bee-paper, if I got more money than I could conveniently spend otherwise!

I will not take space to describe the various work and experimenting that I did, for I found out that if an ordinary rubber ring was dipped in melted beeswax the whole problem was solved, for if the rubber is dipped in wax not a particle of honey will escape, no matter, I believe, how long it is left sealed. I have kept clover honey sealed nearly a year before it candied, and not a trace of honey could be detected on the glass, and the jars were kept bottom side up on purpose to test the matter.

These jars and covers are at present made very cheaply, and sometimes the cover, or rather the underside of it, does not fit down close enough to the glass to enable the ring to seal it tight all around, in such cases of course the defect in the cover has to be remedied, or if not too bad by using two rings it can be sealed tight.

Before filling the jars with honey, or dipping the rings, I took the covers over, and if any are not true, I have a device made to bring them in shape. I then test them by putting some water in a jar, then put on a ring and the

cover, and if no water will leak or can be shaken out, they are all right for honey. I have said this was done before the rings were dipt, for the reason that after they are dipt in the wax, and the cover has been screwed down tight on them, and then taken off, I found in a few instances a trace of honey would escape if the same rings were used without being dipt again.

The wax should be boiling hot when the rings are put in, and they should be simply dipt, and not soaked or cooked in it. Paraffine might answer as well as wax, but it takes such a small amount of wax that the difference in price would hardly amount to anything unless a very large amount of honey was to be put up.

I think there is no doubt but what some kinds of fruits and vegetables contain acids that also act on rubber so that it does not keep the contents of the jar air-tight, and I believe it would pay those who seal fruit by means of a rubber ring, and have trouble because the fruit "works," as I have often heard it called, to give this matter of dipping the rings in hot wax a trial.

This matter is, tho, of but very little interest to me, for I haven't one of those "queens" that are able to put up fruit, and the last two years I have sold what little extracted honey I produced direct to the consumer. Last season I sold at the yard about 1,800 pounds, and could have sold more. It was sold at a low price, but it brought me more than it would if I had shipped it to some city market, or more, counting my time, than I could have gotten for it from grocers.

Southern Minnesota.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

HOLDING THE BREATH TO PREVENT STINGING.

As to that impenetrability theory, on page 294, let every one who inclines to accept the truth of it experiment on his own skin with a fine needle (not so sharp as a bee-sting, but mayhap 'twill answer just as well), and if the needle refuses to go in while you are holding your breath, perhaps the bee-sting will also snub up and refuse to penetrate. But Mr. Raymond is all right. Breathe gently or not at all when your face is close to cross bees; and in extreme cases turn your head away when you must expire.

Per contra, when bees are not particularly cross, I sometimes use my breath instead of a smoker to make them "git furdur."

There is a rationale to the hum in that clipping, and it is this: Most stings which laymen get they bring upon themselves by striking or puffing; and if they were trying *any experiment* that would keep them from doing exasperating things, they would not be stung at all. Some like the old Scotch wizard's magic drop which, held in the mouth while one could count a hundred, made angry husbands mild.

SHALLOW EXTRACTING-FRAMES.

"Tater doesn't think much of shallow extracting-frames, but he's aware he doesn't know much about them—also aware that in a free country others have a right to sit up with them if they want to. If they are to be used, it is fortunate, as Mr. H. H. Porter has found, on page 302, that there is an extractor kept in regular stock that will hold two of them in each basket. As to objections, besides those which readily occur to the mind, bees often hold five or six inches of the lower center of the comb "empty swept and garnisht" in hope that the queen will come up and lay there. With a shallow comb there would only be a little honey in the ends, it seems to me.

WINTERING BEES—SMELTING WORKS.

Mr. Lovesy's contribution to the wintering problem, on page 302, may be important. Some things relative to wintering we are already pretty well at agreement about as the transcendent importance of good stores, and the desirability of occasional flights; but it is still disputed as to where pure air stands in relative importance. Those who reason down from human sanitation to bees naturally in-

cline to one side, while those old practicals who have wintered bees by burying them incline to the other—even if they don't say right out that pure air is of no more importance to a bee than it is to a bedbug. Well, Mr. Lovesy is a man among bee-keepers, and his settled judgment and observation is that bees will not winter at all very near to smelting works which pollute the air with ill gases, and very poorly at considerable distances—even as far distant as his own home is. This seems to show that the bee is more sensitive to impure air than human beings are. Did he lose half the inmates of his home every winter he would be getting out of that. Of the bees he usually loses about half, while at out-apiaries remote from smelters they winter much better with the same preparation.

GIVING SWARMS DIRTY COMBS.

On page 295, Dr. Miller is all right, that combs of simple dead brood (in a *region* where there is no foul brood) may be given to new swarms; yet it would be well to set "Ohio" right as to *how* to give them. He proposes to hive the swarm directly on them, which is not "orthodox." To hive a swarm on, use preferably the best combs at hand for outside combs, and frames with starters or fragmentary combs for middle. Let things stay in that shape till near evening of the second day; then put in your dirty old ones in place of the previous combs or starters. If you want to give a full set of dirty combs, make about three spells of putting them in, on different days.

SUCTION-CLEANING EXPERIMENTS.

C. Davenport seems to be at his best, on page 293, where he gives his manifestly considerable experience in cleaning sections. Queer that so many use sandpaper, and all his sandpaper efforts were failures. Quite likely he is right, that the propolis of some regions is much more sticky and difficult to adapt a machine to than that of other regions. Also, I would add, the propolis of September is much more dauby than that of July. And probably, too, some have reported success when they have not cleaned more than a dozen sections as a basis for their report. And so it is rapidly revolving nutmeg-grater for edges, and rapidly revolving knives for flat surfaces. Why not give up the kinds of super that let bees get at any flat surfaces?

SQUARE CANS VS. BARRELS FOR HONEY.

G. W. Wilson (page 290) would fain have barrels instead of square tins because they are easier to handle. Founding too much on his reason. A couple of square tins box is not nearly so hard to handle as a red-hot cooking-range; and if it's the best package I guess we had better contrive to handle it somehow.

DIFFERENCE IN HONEY AND BEES.

"Many men of many minds." I like the plump impudence with which W. H. Eagerty says there is as much difference in the honey of different strains of bees as in the butter of different breeds of cows. Page 292.

AN EGG-SCATTERING QUEEN.

"When a queen scatters her eggs pinch her head." Henry Alley, who says this, is one of the oldest and foremost authorities on queens. Her majesty should lose no time in deciding that she can do a little better on a pinch.

A QUEER SPRING AND BEE.

When Prof. Cook reports from California that early flowers are late and late flowers early, I guess we shall have to admit that the spring of '99 was a queer spring. And also queer is that bee with one eye centrally located. Page 307.

FLAVOR OF BASSWOOD HONEY.

When we strike a new scheme that's surely going to be gay, how sure we are to omit some little item necessary to success. Mr. Gross, page 290, furnishes an excellent illustration. He saw extracted honey sell for 24 cents a pound in Switzerland, and thereupon sent some. Didn't occur to him that folks in Europe are not accustomed to the flavor of basswood honey. Tater thinks that that strong minty flavor he speaks of in old basswood honey is caused by being extracted too soon. Thick, *thoroly*-ripe basswood honey is delicious when it is old.

AGAVE AND ITS HONEY.

"Nasty" color and mean smell are considerable drawbacks for an ornamental plant. A fluid dram of nectar drawn at one time from four flowers an inch across is "some." These meditations are on the agave plant as

drawn by Mr. Pryal, page 305. He doesn't seem to know whether agave honey is good or bad—few people know, perhaps.

ANENT THE SPELLING REFORM.

"Buki Rold Ots," eh? This is undoubtedly an argument—but an argument greatly overworked—the *look* of words to the eye. Arabic and Chinese print looks repulsive to us, yet attractive to scholarly Arabs and Chinese. And a few years of scholarly attention to Arabic would make its writing look singularly and wonderfully graceful to us. Familiarity, tho not all, is nearly all in this case. Unfamiliarity could no doubt make "Buckeye Rolled Oats" a laughter-provoking line.

DR. MILLER'S EXPERIENCE WITH QUEENS.

I find information for myself in Dr. Miller's experience on page 311 several queens put over a hive to be warmed and fed. The result was the free queen was killed. Bees proceeded on the principle followed by Mrs. Stowe's grandmother, who whipt the innocent boy she could catch because she was infuriated at a rogue that was too nimble for her. Quite likely some harm results, in the form of decreast laying and brood-rearing, in many such cases where the queen is not killed.

GROWTH IN MARKETS FOR HONEY.

Let us have a grain of courage now and then. What's the use of chanting an endless Jeremiad about the failing honey market? This is anent the editorial note on page 312, telling how New York's consumption of honey has risen from 20,000 pounds to 6,000,000 pounds in 38 years—300 fold. We can hardly expect the metropolis to rise another 300 fold; but much of the country, and many towns, *could* do just that. All the trouble was that while consumption grew production bounded—and superabounded. Growth will go on; but the bounding has about stopt.

ADULTERATION OF FLOUR AND SUGAR.

The adulteration of flour with heavy minerals, as related on page 313, is surely a little worse than the adulteration of honey. And if powdered sugar is almost always largely cornstarch, that has an important bearing on the provisioning of queens for journey. COGITATOR.

CONVENTION PROCEEDINGS

Report of the Utah Bee-Keepers' Convention.

A very interesting meeting was held by the Utah Bee-Keepers' Association, April 8, 1899, in Salt Lake City, Pres. E. S. Lovesy calling the convention to order.

The minutes of the October meeting were read and approved, and the following officers were elected for the ensuing year:

President, E. S. Lovesy; 1st Vice-President, George Hone; 2nd Vice-President, R. T. Rhees; Secretary and Treasurer, J. B. Fagg; and Assistant Secretary, G. E. Garrett.

The following County Vice-Presidents were chosen:

Salt Lake County, F. Schach; Utah, Wm. Peay; Wasatch, J. A. Smith; Davis, W. E. Smith; Box Elder, J. Hansen; Weber, O. Folkman; Juab, Thos. Billston; Sevier, C. Canutesen; Washington, Mrs. Woodbury; Tooele, B. Barrows; Cache, Henry Bullock; Morgan, T. R. G. Welch; Millard, S. Teeples; and Emery, Cris Wilcock.

The President's Address.

The outlook for the bee-industry this spring, as far as Utah is concerned, appears to be more favorable than last year. The season last year was short at both ends, the spring was cold, stormy, and late, and while there was a good flow of honey in many parts of the State, it did not keep up as long as usual, especially where the supply of irrigation water was not abundant.

One of the most gratifying features of the industry last season was the firm demand for our products; and the indications are that the demand will be equally good this season, without any regard to the extent of the honey crop. Our bee-products have been pretty well advertised, and

Utah honey is considered par excellence on all markets where it has been sold.

Right here is a point that should be considered: Our bee-keepers should be better organized for the disposing of our products, at least. The old adage, "Every one for himself and Old Nick for the whole," is foolish in this respect, for it often causes a stupid and unnecessary falling of prices. We understand the motto, "By industry we thrive," but if we could put that other grand one in force, "In union is strength," it would be better for all concerned.

Some localities have been considerably overcrowded. There is plenty of unoccupied territory, thus bee-keepers seeking a location for an apiary should carefully consider this question. No one need to envy bee-keepers; as a rule they will earn all they get. Who ever heard of a millionaire bee-keeper? He often flatters himself that he has past the rapids safely to fair sailing, only to be upset and wreckt in the "Slough of Despond." While with proper management it is possible that the bee-industry may be one of the best paying industries in the agricultural line, the few that attain the summit of success do so by an unceasing determination never to give up. Like many other pursuits, bee-keeping is subject to many accidents and disappointments. In some parts of the country we find the winter question one of the most difficult to solve. While it is impossible to give all the causes and remedies, and while location has much to do with this question, protection combined with sufficient ventilation must be observed in the north and central parts of the State. Smelter smoke also seems to be very injurious to successful wintering of bees.

I have received several letters this winter and spring from different parts of the State in regard to losses and trouble thru foul brood, but this matter is in the hands of the bee-keepers in the several counties. The present law will amply protect all bees and bee-keepers, if they will petition their respective county commissioners.

E. S. LOVESY.

Considerable discussion and praise was indulged in in regard to the fine quality of the Utah honey exhibit at the Trans-Mississippi Exposition at Omaha, in 1898, and a general invitation was given to the bee-keepers to exhibit their products at the State Fair next fall.

Christopher Wilcock, of Emery County, gave his experience with foul brood as follows:

Foul Brood.

This is an infectious disease, but is confined solely to the brood, and does not affect the bees. Wherever found it should be dealt with earnestly and with dispatch.

If the colony is weak, I should recommend smothering the bees, and in order to do this without letting a bee escape, take a table-spoonful of sulphur and place it in the entrance of the hive. If there is any breeze, turn the hive so it will blow in the entrance. Then fire the sulphur and it will soon exterminate all the bees. This should be done early in the morning, before any of the bees are flying, as one bee escaping from the hive might carry the disease to any colony with which it may take up its abode.

If the colony is a strong one, I would keep the entrance partly closed so as to prevent any other bees getting in.

Then, as soon as fruit-blossoms come out, so the bees can obtain honey, I recommend saving the bees. In order to do this, and cleanse them from infectious disease, I procure an empty box of any kind, then search out the queen, if possible, and put her in a screen wire cage, which is easily made by taking a small piece of screen, roll it up and tie a string around either end, and place the queen in it, with two or three worker-bees for company; cork them up, and place them in the box, then shake all the bees out of the hive into the box. This should be done either in the evening or early in the morning when the bees are not flying.

Then hold the queen in this box for from 24 to 48 hours, allowing the bees to fly out and in this box as they please. Then take a clean hive with good combs and foundation, and put the bees into it, and they will be free from the disease.

Then take the combs of the diseased hive, and melt them for wax. Be sure to bring it to a boiling heat, which will purify it. Wash the hive thoroly with boiling water, and also everything pertaining to it that you wish to use again. My experience is that this method strictly carried out will effect a cure.

C. WILCOCK.

E. S. Lovesy said that with the excellent law that Utah has on this subject, and with the improved methods of handling the disease, there should be no serious trouble in

keeping it down. Our law is so well worded that our bee-keepers don't have to wait for days or weeks before it can be applied; and while it can remain dormant when not needed, it can also be applied for the benefit of any bee-keeper in any county, and at any time, by making application to the inspectors in their respective counties or district. There doesn't seem to be any trouble in regard to the matter except in a few places where the bee-keepers have not taken action to get the law in force. Probably if the bee-keepers thru the State will take an interest in the matter for their own benefit, it is possible the whole thing could be stamp out.

Some very interesting remarks were made by Vice-Presidents Hone and Rhees, and also by Mr. Teeple and others, on the wintering of bees on the summer stands, and also by the house and cellar methods. They also showed the necessity of ventilation to prevent dampness.

Messrs. Schach, West, Dudley, and others spoke on the necessity of a more united action in the purchase of supplies, and in disposing of the bee-products. Mr. Folger and others spoke on the best shape and style of hives, and also in praise of Utah honey.

Messrs. Hone, Fagg, Garrett and others gave their views on the foul brood question. They claimed that all bee-keepers, as far as possible, should study this subject for themselves. After some further remarks by several members on general topics the meeting adjourned until October, 1899.

It was one of the most largely attended meetings ever held by the Association—some 30 members being present; and the interest and participation in the proceedings were general. It is hoped that it will be the means of forming a stronger bond of union among the bee-keepers of the State.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Pure Italians, Five-Banders and Albino Bees.

On page 306 appears a series of questions for me to answer, which would have been answered sooner if the editor had sent them directly to me instead of first putting them in print. In order to save room I'll not repeat the questions but answer in order:

1. I have seen Italian queens that I had good reason to believe came from Italy, and I have seen their progeny, all of which I believe to have been pure, but I don't know that I ever saw a worker-bee that first saw the light in Italy.

2. I use the word "pure" in its usual sense, a pure Italian being that which is unmixt with something that is not Italian.

3. I suppose changes come about in bees as in other things. The people in the world don't all look just like Adam and Eve, altho I believe Adam and Eve were pure stock. The more fixt the type, the less likelihood of changes. I do not believe pure Italians are so fixt in character as pure blacks, hence it is easier to breed different strains of Italians. While it may be true that the Italian is not a pure race, I should consider it hypercritical to say our queen-breeders had never bred pure Italians.

4. As I said before, I don't know that I ever saw any bee except a queen that came from Italy. But I believe that there are also workers and drones in Italy.

5. As I don't think I ever saw a worker-bee that came from Italy, I can hardly tell much about its color.

6. I have seen a great many bees with three yellow bands that were the progeny of what I believe were imported queens.

7. I mean by "bands" the same as is meant by the word as used in general by all writers on bee-culture—the segments or stripes of the abdomen.

8. Yes, I saw that question-mark.

9. Yes, I have seen a great many single bees from an imported queen that had three yellow segments.

10. No, I don't know that I ever saw a single bee from an imported queen that had three segments all of a maroon color. In fact, I think the color was always more nearly yellow than maroon, perhaps the color of yellow ocher. It is possible, of course, that I may be mistaken as to the matter of color, having no specimen before me, but that's as nearly as I remember, and I think all the authorities that I've read teach the same thing.

11. Not having a specimen before me, I cannot answer minutely your question, but this from Cheshire may answer the purpose in describing the three yellow bands: "The first three rings are themselves in large part a transparent, tawny yellow transparent, as may be seen by allowing a bee to fly on the window-pane. The first abdominal ring on the dorsal side mainly faces the thorax, and may be mist by careless observation; its lower edge only is black. The upper two-thirds of the second is yellow, the upper third smooth and hairless, because this passes beneath the ring above it when the body is contracted. A band of yellow hair covers the second third, and adds much to the beauty of the bee, as hairs and ground are alike yellow. The lower third of the ring is glossy black, carrying many microscopic hairs, and a minute fringe. The third ring resembles the second, while the fourth and fifth carry yellowish hairs, but are black. The sixth ring, black also, is nearly hairless."

12. I think the tendency of Italians bred in this country is toward a lighter color.

13. I think I never disputed that in the five-banded bees, one, at least, of the bands may have been solid yellow without any black.

14. I don't know that I ever saw a worker-bee with the sixth segment yellow. I think, however, that I have read of workers yellow to the tip so often that I took it for granted that such were in existence. If there are none such in existence I am thankful for the correction, for there are many things I don't know about bees, but about which I am anxious to learn. Possibly those who spoke of workers yellow to the tip were speaking in a slightly exaggerated form, somewhat as you do when you speak of a worker appearing like "a lump of gold." We mustn't be too hard on them.

15. I have seen what was called an albino bee.

16. I think the part that lackt the coloring-matter was the hairs.

17. If you mean the coloring of the chitine, I don't think that there was any change in that in the albino. A lack of coloring-matter in the hairs made the bands or segments lighter.

I said that "albinos among bees are much the same as albinos among the human race—bees which have been so bred that the coloring-matter is somewhat lacking." If I had stopt at the first half of that statement, there would be some show for pretending to think I meant a bee milky-white all over, but as I immediately stated in the last half that I meant "bees so bred that the coloring-matter is somewhat lacking," I think my statement is entirely correct.

If I desired to be as critical with your writings, I think I could find some spots that would not bear that kind of scrutiny. For example, you say, "I had supposed that the abdomen of each bee was composed of six horny segments." Now, if I wanted to pick at that, I might say, "You are quite mistaken if you think there is nothing of the abdomen but six horny segments. There is the framework or skeleton composed of chitine, inside of that a whole lot of inwards, and outside more or less hairs or down." But I don't think it would be very nice of me to talk that way. I think you and I will do well not to descend to hypercriticism.

C. C. MILLER.

Building Comb in All Shapes.

I have $\frac{3}{4}$ -inch starters in my extracting-supers, and the bees are beginning to build comb. Some begin on the starters and some on top of the bottom-bars and build up; and some build rather across the bottom-bars— all shapes. What's the matter? What must I do? So, CAROLINA.

ANSWER. Very likely the reason for your bees doing as they have done is the great distance from the brood-nest to the starters. If the frames in the super are of the same depth as in the lower story, it's a pretty long stretch from the brood-combs to those $\frac{3}{4}$ -inch starters. So the bees build up from below, just as they would if no starters were present.

If you will persistently tear out all the work they do in

the wrong place, leaving only that which is begun on the starters, they will finally give up and build where *you* want the building done. But after they commence working in a certain way they are somewhat stubborn about changing. There would probably be no such trouble if the frames were entirely filled with foundation, or even if two of the central frames were thus filled. You will make a very sure thing of it if you put a comb of brood in the extracting-super (on the supposition that the super takes the same size of frames as the brood-chamber), either a comb filled with brood or honey, or an empty comb. This comb may be removed, if you so desire, after the bees have begun work thoroly in the super.

Selling Honey Cough Medicine.

I make a very good cough medicine of honey, and have so many calls for it that I cannot afford to give it away any longer. Would I be liable to a fine if I should take a few cents for each package to cover expense? If the law in regard to making and selling medicine is likely to be different in Minnesota than in Illinois, whom should I consult to find out?
MINNESOTA.

ANSWER.—The probability is that there never would be any trouble about your selling a preparation of the kind, but any lawyer or justice of the peace ought to be able to tell you about the law in your State.

Using Moldy Combs Sun Wax-Extractor.

1. I had two colonies of bees that died, and some of the honey is sour and working. Would it be all right to let the bees clean it up and then hive bees on it when they swarm? The combs have a lot of bee-bread in them, and there is a lot of mold where the bee-bread is. Will the new swarm clean it out, or what should I do with the combs? I wintered my bees in the cellar.

2. How can I make a small sun wax-extractor? IOWA.

ANSWERS.—1. Don't put a swarm on these combs that are sour and moldy, for fear the bees would object and abscond. But let the bees first clean them up, and then they will be all right for swarms. The best way is to put a hive full of the combs under a strong colony. Do so toward evening, so that robbers will not trouble, especially if bees are not gathering much at the time.

2. The simplest and cheapest way to make something small is to take an old dripping-pan torn open at one end, or almost any other dish of the kind, or even a piece of old stovepipe flattened out, put it in a box and have it slanting enough so the melted wax will run off one end, and have a dish beneath to catch the wax, then put the bits of comb on this upper surface and cover the box with a pane of glass, setting it in a sunny place, preferably beside a south wall.

Wax from Foul-Broody Combs, the Editor of *Gleanings in Bee-Culture* thinks, should not be rendered because of the possible danger of infection. Surely it is better to err on the safe side. Better burn all such combs and run no possible risk by having such wax made into foundation.

Buckwheat in Dry Weather.—Editor Holtermann, of the *Canadian Bee Journal*, has had experience in moving bees for fall pasture, particularly to buckwheat fields, and he says it is not worth while to move to buckwheat fields, especially those on sandy soils, if there is a prolonged dry time.

Immunity from Foul Brood.—Prof. Henry W. Brice gives in the *British Bee Journal* as one of the most interesting facts in connection with the subject of foul brood, the immunity of certain colonies in an apiary, even in centers where the disease is widely prevalent. This may be chiefly attributed to the very healthy condition of the colonies, but let chilled brood be found in one of these colonies,

and the unhealthy condition thus introduced makes the immunity cease. Perhaps it is the stretching of this a little too far that makes some good men believe that chilled brood may of itself originate foul brood.

Coffee and Honey.—A writer in *Bee-Chat* says that in Jamaica a large amount of honey is stored while coffee is in bloom, there being three or four blossomings of three or four days each in a season. On a coffee property where 100 colonies of bees were kept there had been no light coffee for two crops, while 8 or 10 miles away they had 40 to 50 bags of light coffee.

Somerford's Plan of Forming Nuclei, lately mentioned as having been given in *Gleanings in Bee-Culture*—by shutting up the nuclei with green leaves till they gnawed their way out—E. T. Flanagan says in that paper has been much practiced by him, but great caution is needed in warm weather, for he has known many nuclei to be utterly ruined, especially very strong ones, presumably by smothering.

Heavy Loss of Bees by Fire.—*Gleanings in Bee-Culture* reports that T. F. Bingham, he of the Bingham smoker, had 80 colonies of bees burned by means of a spark from the railroad. No particulars are given, but it may be wise for us to be on guard as much as possible against such things. A bee-hive with its contents burns readily, and it is not well to have hives so close together that fire will readily communicate from one to the other, neither is it well to have the ground between the hives covered by dried grass or other combustible material.

Milkweed Honey.—On page 798 of this journal for 1898, Dr. Miller made a guess that milkweed honey was amber. Clark A. Montague says in the *Bee-Keepers' Review* it is nearly as light as basswood, a correction that Dr. Miller will no doubt cheerfully accept, as Mr. Montague is in northern Michigan, in a locality where he gets an annual average of 100 pounds per colony, spring count, from milkweed alone! As to quality, he says: "We think it is the best honey we have, altho some prefer the stronger flavors of basswood or buckwheat."

Water for Bees in Spring is the theme that occupies in the *Bee-Keepers' Review* the department of "Good Things from Other Journals." Dadant's Langstroth is quoted as calling attention to the large amount of water used in brood-rearing in the spring, and the danger that many bees will be lost if obliged to go a distance for it on chilly days. One writer advises to give both fresh and salt water, so the bees can have their choice. Dr. Mason says his bees in the cellar took water greedily at the entrances of the hives, when it was given to them *warm* in a sponge.

Shortened Top-Bars.—When a top-bar is so long that not more than 1-16 inch is allowed for play at either end, the gluing up of this 1-16, more or less, is perhaps the largest factor in making the frames difficult to move. To obviate this difficulty, especially in the case of hives with metal rests in the rabbets, the ends were made shorter, and a staple driven in the end-bar under the top-bar at each end to space the frame endwise. Some fear was entertained that there would be trouble about frames dropping down in the hive whenever they were moved so as not to be square in place. C. Davenport says in *Gleanings in Bee-Culture* that in actual practice there is no such trouble, and as no complaints have appeared from others he is probably correct. Even when a frame is filled with brood and honey, the ends can be sawed off and the staples driven in.

Travel-Stain has been a matter of considerable discussion lately. After what has been said by J. E. Crane and others, D. W. Heise, in the *Canadian Bee Journal*, thinks it time to bid good-by to the term "travel-stain" as being misleading. Now comes a brand-new theory with a brand-new discovery of a special secretion by the workers, according to S. P. Culley, in *Gleanings in Bee-Culture*, which secretion is the guilty culprit in cases where the substance of the comb is colored thru and thru. The honey is also colored by this secretion, which accounts for the fact that honey is darker when gathered slowly. This Boiler does not pretend to have proof that such a thing is impossible, but would be far from endorsing Editor Root when he says it "appears very reasonable." Cheshire's explanation that the coloring is due to the dejections of the larvae seems a good deal more reasonable.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

JUNE 22, 1899.

NO. 25

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Shall We Get Apis Dorsata?—Editor Hutchinson, of the Bee-Keepers' Review, expresses himself on this subject in the following language:

"There has been a whole lot published in the bee-journals about the bringing here of *Apis dorsata*. If any one has opposed it, he has been accused of having some personal feeling in the matter. To speak real plain, some folks may not like Frank Benton, and they might not like it if he got the job of going after these bees. If anybody opposes the bringing here of *Apis dorsata*, somebody else is almost sure to hint that enmity to Mr. Benton is the real cause of their opposition. Mind you, they *hint*; they do not say it right out so that it can be disputed and combated. Some folks may not like Mr. Benton; at the same time he is probably the most competent man to send after *Apis dorsata*. It is possible that a few, and a *very* few, would oppose the choice of Mr. Benton as the man to send after these bees; but I very much doubt if any man has opposed their introduction on those grounds—even in his own mind.

"I have always opposed their introduction until we know more about them. I am not opposed to progress, nor the introduction of new things of the desirability of which we are assured, or that can be kept under control until the desirability is no longer an unknown quantity."

As we have been among those who have pretty strongly opposed the introduction of *Apis dorsata* into this country, and as it is also pretty generally known that Mr. Benton has little use for us, perhaps a few words further from this office will be in order.

Firstly, if anybody is to be sent by our Government to

get *Apis dorsata*, we don't hesitate at all in saying that Mr. Frank Benton is the very best man for the purpose. He is the only American that ever succeeded in capturing and hiving *Apis dorsata*, and perhaps has had a larger experience with foreign races of bees than any one else on earth.

But, secondly, we have contended all along that *Apis dorsata* should first be thoroly experimented with in their native habitat, and then, if found valuable enough to be worth while, by all means get them into this country. There's where we stand.

"Fashionable Honey."—Mr. L. C. Salsbury, of Bradford Co., Pa., sends us the following taken from the Philadelphia Press, of June 8, with the heading, "Fashionable Honey:—"

Honey—and it must be of the newest and most delectable flavor—is claiming just now an unusual amount of attention at the fashionable breakfast table. In fact, its place there is becoming quite as undisputed as that of wines at dinner parties. Men of wealth and leisure are assiduously testing and experimenting with the different brands of honey, and wrinkling their brows over the problem of producing what seems to them the most desirable flavor during the coming summer.

For the bee is no longer allowed to pursue its own sweet perigrinations, and sip of the nectar of flowers wherever it chooses. Its actions are restricted and guided. As a result, such honey as never was tasted before is offered at smart tables.

If it is the white sweet clover flavor that has gained favor with the epicure, he goes systematically to work to produce it; and plants, at his country place, a large plot of ground—perhaps half an acre—with this particular kind of clover. He has it carefully kept from weeds or any other variety of clover that might endeavor to find a footing there. The whole bed is enclosed and roofed with a fine wire netting, and the bee-hives are then placed within the enclosure. Try as it will, the bee can produce none other than white sweet clover honey. In flavor it is very delicate, and almost white in color.

Yellow sweet clover honey is preferred by others. The flavor is slightly stronger than that made from the white variety, and its color is a deep yellow.

Then there is the honey that is made from such flowers as thistles and milkweeds; it is most amusing to hear producers of such flavors tell of their tribulations in making these wayward plants grow within their restriction. Some of the wild-flower honey is almost black in color, and the flavor is certainly very different from what it was in the days when honey was honey, and that fact settled the question.

How is that for a sample of the stuff the daily newspapers are furnish with? The idea of a half acre of clover, and that roofed with fine wire-netting to keep the bees to work on! Then, whoever saw any surplus honey that they knew was gathered from the yellow sweet clover?

The whole thing is a fair sample of the average newspaper reporter's effusions when he gets outside of his field—that of reporting baseball games, political caucuses, etc. The ordinary newspaper writer should know better than to get very close to the bee-subject, else he may be subject to such a fit as the one must have fallen in when he wrote about "fashionable honey" in such an unfashionable and untruthful way.

Investigation of Adulterated Foods. On page 328 we referred to the investigation of adulterated foods being conducted in this city by a committee appointed by the United States Senate. That committee is composed of the following senators: Mason, of Illinois; Harris, of Kansas; Wetmore, of Rhode Island; Smith, of New Jersey; and Cannon, of Utah.

After taking a recess of two or three weeks the committee resumed their investigations for a few days, again adjourning on June 8. In an interview published in the Chicago Record of that date, Senator Mason was reported to have given utterance to the following very strong language:

"I have been badgered and browbeaten by manufacturers of adulterated foods until I am tired. I have been threatened by political destruction, and been approached by bribe-givers until I feel it my duty to await the presence of other members of the committee before taking further testimony. There is one concern in this city that has already threatened to ruin me—the glucose trust.

"It is the old story of the flour bill. I stood by the bill for unadulterated flour, and have always believed I compelled its passage. At that time the glucose men did everything in their power to frighten me, or in some other way get me off the track of my purpose. Why, they even went to my son, who was newly wed, and had only a scant home for himself, and offered him a salary of \$10,000 a year to act as attorney for them, making the implied condition that he should haul me away from the support of the flour bill. The adulterators of food products are pursuing similar tactics to-day, and that is why I am determined that before the investigation proceeds further, fellow-members of the committee must step in and share the burden of responsibility.

"Testimony that has been absolutely of no value has been admitted by me simply because I did not wish to accept the responsibility of excluding it. I have not wished to take the risk of having it said that I excluded testimony that might explain alleged evil conditions. I knew the testimony could avail nothing, but admitted it in order that there might be no opportunity for the charge of prejudice. Had there been other members of the committee to support me, this time would not have been wasted. Still, I cannot say that much time has been wasted, because I have gathered enough evidence to form the foundation of a bill to compel every manufacturer of food products to label all food according to its composition."

So the glucose trust is beginning to make its threats. All right; before they get thru it (the trust) will have a few scores to settle with the bee-keepers of this country. Glucose is the principal adulterant found in the so-called "honey" mixtures offered for sale in so many grocery stores in Chicago and other cities, and some of these fine days some one will be compelled to stop that criminal practice, or work for the State awhile for nothing. We believe it will not be very long until we have a strong national law against adulteration, and then we will see whether Mr. Glucose Trust will "threaten to ruin" anybody. About that time it will likely be ruined itself.

The Boston Transcript, some time ago, published the following paragraph, which gives quite a little information about glucose, and the extent to which it is manufactured and used as an adulterant in this country:

WHAT GLUCOSE IS MADE OF.—Commercial glucose is made from corn, but it may be got from almost any sort of vegetable stuff. It may be obtained from cotton rags by mixing with the rags a small quantity of sulphuric acid. Ordinary blotting paper treated in the same way will yield glucose. Cotton rags and blotting paper are cellulose, and cellulose is the same thing chemically as sugar, save that it contains more water in each of its molecules. The sulphuric acid takes away the extra water, and the residue is glucose. Glucose is not quite so sweet as cane-sugar, but it costs only about one-fourth as much per pound. So it makes a very suitable adulterant, and for this purpose it is widely employed in the manufacture of candies, jellies, syrups, etc. It would be made out of rags but for the fact that corn is cheaper than rags. Ten pounds of glucose are turned out annually in this country for every man, woman and child in the United States—a total of 650,000,000 pounds. In fact, it is the most widely employed of all adulterants.

So glucose is more used than any other product by adulterators, and in order to sell it it must be past off under the name of something better, such as honey, syrup, jelly, etc., and thus defraud the public. We would advise the glucose trust to put their trust in some more honorable article. Glucose is too great a defiler of the pure and the good.

To Close Saturday Afternoons.—We wish that beekeepers (especially those in or near Chicago) would hereby take notice that the offices of the American Bee Journal and Root's Chicago Branch of bee-keepers' supplies will be closed Saturday afternoons during July, August and Sept.

REV. CHAS. HORACK, of LaSalle Co., Ill., called on us June 10. Mr. Horack preaches to a Bohemian congregation, and keeps a few colonies of bees for recreation.

MR. W. T. RICHARDSON, of Ventura Co., Calif., president of the California Bee-Keepers' Exchange, wrote us June 5: "We shall not have any surplus honey this year."

MR. J. H. STOCK, of Erie Co., N. Y., has sent us a photograph of his apiary of about 20 colonies. We are glad to get pictures of the apiaries of our readers, some of which we are able to have engraved so as to reproduce them in the Bee Journal. But for engraving they must be very clear and distinct. Poor photographs cannot be "half-toned" very satisfactorily.

ALICE JENNINGS—evidently a little city girl—writing about bees, had this to say about them:

"Bees are always busy because the idle ones are killed. They make honey and wax, but paraffine candles are cheaper, or else candles made out of whales. The bees build cells and combs, and sometimes fill trees, and bears smell the honey and eat it. They suck the juice out of flowers, and the flower dies. Bees are meaner than mosquitoes, and you can tell them by the yellow bands on their abdomen."

MR. CHAUNCEY E. ANDERSON, of Lucas Co., Ohio, sends us a clipping from the Toledo Blade, about bees storing honey in a sponge that a certain New Englander put into a hive. The idea is to fill a hive with sponges, then have the bees fill them, and afterward squeeze out the honey, thus saving the comb-building. We can hardly conceive of anything more ridiculous or foolish. The whole thing has every appearance of the usual newspaper yarn.

Mr. Anderson reports the prospects good for a splendid honey-flow in his locality this year.

MR. FRANK BEERS, of the firm of E. A. Beers & Co., doing a general merchandise business in Uinta Co., Utah, called on us June 10, having come to Chicago about a week in advance of a carload of fine alfalfa extracted honey of last season's production. Mr. Beers' firm expects hereafter to represent the bee-keepers of his locality in the marketing of their honey. He has been instrumental in organizing a local bee-keepers' association numbering about 25 members. We wish both the firm of Beers & Co. and the bee-keepers all the success they may anticipate.

MR. W. E. HATTERMAN, a bee-keeper of this (Cook) county, returned from a visit to Porto Rico a few weeks ago. He is simply overwhelmed with the beauty of that new possession of Uncle Sam. He doesn't believe that there are two colonies of bees in modern hives on the whole island. All are wild, living in the trees, and whenever any honey is wanted, the natives must first go out and find a bee-tree! Mr. Hatterman thinks it would be a grand place for up-to-date bee-keeping. He traveled over a good portion of the island on horseback, and found in endless profusion nectar-yielding plants of many varieties. He was delighted with the climate, and says he is going back some day.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

The Premiums offered on page 385 are well worth working for. Look at them.

Eighty Colonies on 8 Frames, or 40 Colonies on 16 Frames Which?

Query 93.—Which will give the apiarist the better results, 80 colonies on 8-frames, or 40 colonies on 16-frames in two stories, time, labor and expense being equally computed?—Ohio.

Eugene Secor—The former.

P. H. Elwood—80 colonies on 8 combs.

A. F. Brown—The 80 colonies, I believe.

Mrs. L. Harrison—I would take the 8-frame.

W. G. Larrabee—I should say 80 colonies on 8 frames.

Dr. C. C. Miller—That depends. Generally the 80 8-frames.

J. M. Hambaugh—Financially, 40 colonies on 16 frames, I believe.

Dr. J. P. H. Brown—It will depend on location and management.

Chas. Dadant & Son—8 frames are too few; 16 frames are too many.

Mrs. J. M. Null—80 on 8 frames will double 40 on 16, in my experience.

O. O. Poppleton—I do not practice tiering up of hives, and cannot answer.

G. M. Doolittle—For comb honey, the former; for extracted honey, the latter.

S. T. Pettit—The question is too indefinite. Very much will depend upon the size and shape of the frame. If the Lang-

Extracted Honey Wanted

As soon as you have any good, well-ripened Extracted Honey for sale, send us a small sample, stating quantity, price expected delivered in Chicago, and how put up. Prefer it in 60-pound tin cans. Expect to be able to place car-load lots as well as smaller shipments of Extracted Honey. But don't ship us any until we order. Address,

MAIN OFFICE AND WORKS:
MEDINA, OHIO.

stroth is meant, the 80 colonies will be away out of sight ahead; that is, all things else being equal.

E. Whitcomb—80 colonies in two-story 8-frame hives, every time, if the pasturage is ample.

D. W. Heise—I would prefer the 40 colonies on 16 frames, every time, the way I am situated in this locality.

Emerson T. Abbott—It would all depend upon the way they were manipulated, and the nature of the honey-flow.

E. France—40 colonies on 16 frames; or, better still, have 3 stories, or 24 frames. I have reference to extracted honey.

Prof. A. J. Cook—Can't be answered. Working for comb honey, the first; for extracted, we must have the two stories.

Mrs. A. J. Barber—For comb honey, I would want 80 colonies in 8-frame hives. For extracted honey, I would double them up.

J. A. Stone—The one is too small, and the other too large, but I would (just a guess) think the 80 colonies with the 8-frames.

R. L. Taylor—The 80, of course—twice as much if they are equally as good in April, and you give them room for surplus as they need it.

C. Davenport—There is no question but what better results could be secured with the larger number, for comb honey, in my locality.

J. E. Pond—This is a much mooted question, and a correct solution might depend upon locality. For myself I prefer the 10-frame hives, every time.

R. C. Aikin—Here, I believe the 40 colonies on 16, but I cannot understand what you mean by "equally." Suspect some fields would be different.

Dr. A. B. Mason—It will depend upon the locality and the apiarist. For myself and my locality, the better results will be with 80 colonies on 8 frames to each colony.

C. H. Dibbern—If you produce comb honey I should say the 80 8-frame hives, and for extracted the 40 16-frame hives, if the colonies were correspondingly strong.

Rev. M. Mahin—There are so many things that naturally enter into the case that the answer is very difficult. With a good season, and in a good field, working for comb honey, I would use the 80 colonies in single-story hives.

E. S. Lovesy—Why, the 80 colonies, every time. Have the frames straight, and keep all colonies strong, and there would be no comparison, as with proper management it would be impossible to produce the same results with 40 colonies as you can with 80.

Adrian Getaz—I suppose that the total number of bees is to be the same in both cases, and therefore each 16-frame colony has twice the number of bees that each 8-frame colony has. If such is the case, I should say unhesitatingly that the 16 frames will give the better results.

G. W. Demaree—There is too much difference in the influences of locality to answer this question so as to benefit many people. If I had 80 colonies, or 800 colonies, of bees in 8-frame hives, I would have to go to the expense and labor of transferring them to larger hives to suit my locality. Eighty colonies of bees in 8 frame hives in my locality would send the owner to the asylum every good honey season.

The Mysteries of White Clover.

Red clover was badly killed out in this region last winter, but white clover seemed to come out all right, making a fine show of promise. Favoring rains brought it forward in very thrifty condition, but still the question would thrust itself unpleasantly forward. Will the bees get any honey from it? May 26 the first blossom put in an appearance, and others followed in unusually rapid succession, so that in a very few days the pastures and road-sides were as white as they had ever been in the best years. But the bees didn't seem to be greatly interested, and by June 6 I was forced to the painful conclusion that there was "nothing in it" for the bees, as the combs were empty of honey and the bees were robbing wherever they had a chance.

Suddenly, and with no apparent reason for any change, on June 7 the bees began to tumble over one another in their haste to garner the precious sweet, and the present outlook is good for a crop.

If any one has a key to unlock the mysteries of white clover as to yielding or refusing to yield honey, I wish he'd lend it to me.
C. C. MILLER.

McHenry Co., Ill., June 9

Good Prospect for Honey.

My bees come thru the winter all right, losing 2 colonies out of 40, others lost from half to all. I attribute my success to the "Old Reliable," and a good, well-ventilated cellar. Prospects are good for a large yield of honey. The worms that have destroyed the basswood the past three years have nearly disappeared.
J. H. DOTY.

Polk Co., Wis., June 5.

Gathering White Clover Honey.

Our bees are in a perfect whirl gathering white clover honey. No swarms yet, but a fine start in surplus.

N. A. & M. M. ROBINSON.

Clark Co., Ill., June 5.

A Backward Spring.

We have had backward weather this spring. Bees got very little honey during fruit-bloom, on account of frosty nights. White clover has commenced blooming, and I see the bees are bringing in some honey now. Alfalfa will be in bloom in two weeks. The indications now are that we will have a good season for the bees remaining. The winter losses were quite heavy; some places very much so.

ELIAS JOHNSON.

Utica Co., Utah, June 2.

A Beginner's Experience.

I am only a beginner in the art of apiculture, but as far as I have had anything to do with bees, I have had a pretty good success. This is my fourth year, and I can say that we have had all the honey that we can eat. I started in with only one colony, and the first year I received a surplus of about 60 pounds of comb honey. The next year I started in with the same colony, as it did not swarm, and I received 123 pounds of comb honey. Last year I transferred some bees for a man for the half, and increased my colonies to nine. I received last year 264 pounds of comb honey.

My bees wintered well last winter, and came out without loss. I winter them in double-walled hives. There was some loss of bees in wintering in this locality, but not very severe. Most of the people who have bees here use the old out-of-date box. There are, however, some practical bee-keepers here, who are up-to-date in their hives and

Please Mention the Bee Journal when writing Advertisers.

in their manipulations. There are about 1,000 colonies of bees in this county. About 8 out of 10 do not know how to take care of their bees. I was asked by two persons to-day, who have bees and want me to transfer them in a movable-frame hive, but I have no time to do it. It would be a good thing if they would take a good bee-paper.

Our honey season has opened, and my bees are working in the supers. The outlook at present is for a fair season of white clover, as it is now in full blast, and the bees are working strong. Last year it was a total failure. Our largest honey crop, however, is in the fall from Spanish-needle. The swarming-season is here also, and quite a number report that their bees have swarmed, but I have not had any swarms yet. I try to keep my bees from swarming, as I do not wish an increase in bees, but an increase in honey. Young swarms can be bought for from 50 cents to 75 cents. I keep my bees in town, for enjoyment, and to have something to eat on the table that is good three times a day. C. I. ELROD, Clay Co., Ill., May 27.

Lost Heavily in Winter.

We are numbered among the many who lost quite heavily in bees, having lost 36 colonies out of 84, and up to date we have not had any swarms issue, but are looking for them every day. CRAWFORD BROS., Oscoda Co., Mich., June 4.

Yellow Sweet Clover, Etc.

I have located several square rods of yellow sweet clover, and will try to get my place seeded to it. I will send a sample of the bloom. It commenced to bloom about May 10. Our bees are doing well, having wintered finely on the summer stands in single-walled hive. A. H. COSNOW.

[Thank you for seeding the sprig of yellow sweet clover bloom. We would like to get a quantity of the seed of this variety — EDITOR.]

Yes, I Would!

It is perhaps best that I am not an autocrat for even an hour. If I were, there is one class of brutes that would never forget me, tho' ever so busy keeping their feet from scorching.

I refer to those big, muscular people, full of wrath and ignorance, whose favorite method of punishing children is to viciously box their ears. Perhaps the offense committed is slight, but the child soon feels a violent shock on the side of the head, as if inflicted by a 10 pound ham! What injuries that brute has occasioned he may never know, but the poor, defenseless child may be made completely deaf the rest of his life, or even made a victim to epilepsy thru injury to the tender, formative brain. DR. PEIRO.

Thinks the Prospects Fair.

Bees are doing very well now. Swarming is commencing in earnest. My first swarm came out May 25. White and Alsike clovers are commencing to bloom. Altogether, I think the prospects are fair. IRA LUBBERS, Sheboygan Co., Wis., June 7.

Bees All Right—Good Prospects.

My bees are all right. Out of 16 colonies I lost none, but some bee-keepers lost the most of theirs, and yet some of them know ten times as much as I do. Honey prospects are good now, but what we will get is another thing. CHARLES LEHN'S, Kankakee Co., Ill., June 6.

A Bee-Killer.

I send you by this mail one of the bee-killers. Contrary to common opinion they are quite numerous in this section. I have killed a good many of them—as many as

AUGUST WEISS, Hortonville, Wis.

The Oliver Typewriter.

IT TOOK 25 YEARS to find out that typewriters have been built up-side-down. The OLIVER is built right-side up, where the WORK IS IN SIGHT. THE OLIVER IS POPULAR because it is an up-to-date typewriter, not in the Trust, and because it SHOWS EVERY WORD AS YOU WRITE IT.

Honey and Beeswax Wanted.

15Att Please mention the Bee Journal.

CHAS. F. MUTH & SON.

I wish to announce to my friends and patrons that I have this day sold to C. H. W. WEBER, of Cincinnati, my Honey and Bee-keepers' Supply business, known for the past 38 years as CHAS. F. MUTH & SON. Mr. Weber will continue to push the Langstroth hive and everything pertaining to same; besides, he has secured the agency for Mr. Root's goods, and will sell them at his prices. I beg the customers of the old house, to whom I wish to extend my thanks, to continue their patronage with Mr. Weber, by whom I am sure they will be accorded fair and honest treatment.

MRS. ANNIE MUTH (Widow.) Cincinnati, Ohio, April 7, 1899. 15Att Please mention Bee Journal when writing.

YOUR WAGON WHEELS
may need new rings, new spokes or new tires. These repairs have to be made every little while with wooden wheels. To pay all this expense for all time by buying a set of our **ELECTRIC Steel Wheels**
They are made with direct or staggered oval spokes, broad tires, any height, and to fit any wagon. They don't rot, get to spikes and need no tire setting, last indefinitely. There is only one thing better, and that is an **ELECTRIC HANDY WAGON.** Our free illustrated catalogue tells all about both and gives prices. Send for it.

seven at a time. They look so much like bumble-bees that most folks don't know the difference. I have seen them with bees which they had caught, also horse flies and bugs. They look and fly very much like the drone of the bumble-bee, but come in June instead of toward fall.

W. C. LYMAN.

DuPage Co., Ill., June 6.

[The sample bee-killer came all right. It does look very much like a bumble-bee.—EDITOR.]

Half the Bees Lost in Winter.

The bees that got thru the winter are doing finely here now. They will be swarming in a few days. White clover is commencing to bloom, and there will be a fine crop of it. Fully 50 percent of the bees here were killed in the cold-snap we had in February.

I cannot get along without the old American Bee Journal. **W. L. SMITHEY,** Monroe Co., Mo., June 3.

Good Prospects for Honey.

The prospects are good for honey this year. White clover and motherwort are yielding honey very profusely at present; linden will bloom shortly. It was a tough winter on bees here. I lost about one-third of mine, and my neighbors nearly all they had. I sell my honey for 10, 12½ and 15 cents a pound; my neighbors sell theirs for 8 and 10 cents, and it is a slow go at that—chunk honey taken from the old fashioned "gum."
WILL J. EVANS, Cannon Co., Tenn., June 5.

Wintered Out-Doors Without Loss.

My bees came thru the winter full and strong on the summer stands, without any loss. They brought me the last honey and pollen Nov. 23, 1898, and the first this year on April 10. The winter for bees was nearly one month longer than last. My first swarm came out May 23, only three days later than last year. I have had swarms every day since. After 60 years among the bees I have learned how to winter them on the summer stands without any loss. The method is easy and sure. There should be no loss of bees during the winter months.
DAVID H. METCALF, Calhoun Co., Mich., June 6.

[We should be pleased to give your wintering method a place in these columns, Mr. Metcalf.—EDITOR.]

Basswood Will be Late.

The prospect for a honey crop is good here. Clover is blooming now, and so far the bees have worked on it, tho it cannot be depended upon. Basswood is full of buds, but it will be late this year. It is a pity so many bees have died—I think more than half in this section. Some bee-keepers lost all they had. Surely, honey will bring a better price.
GUSTAVE GROSS, Vernon Co., Wis., June 11.

Heavy Loss of Bees in Winter.

I can't get along very well without the old American Bee Journal. There was a heavy loss of bees in this locality last winter. I got thru the winter very well. My bees were on the summer stands, and I lost 7 colonies out of 80. My bees are in very good shape, and not swarming much.
D. J. MCINTURE, Harlan Co., Nebr., June 9.

Best Honey-Flow in Six Years.

We have not had such an unprecedented flow of honey since 1893. Ever since spring opened the flow has been almost continuous. I commenced keeping bees in 1863, and have been at it more or less ever since. I began in 1898 with 6 colonies, wintered 15

The Novelty Pocket-Knife

(A heavier and stronger knife than the one we offered heretofore.)

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the Subscriber.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the Novelty is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the Novelties, your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be apprised of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00), and we will also send to each new name a copy of the Premium Edition of the book, BEES AND HONEY. We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Order Early

There are indications that the demand for SUPPLIES will be very large this season, and everyone should order as early as possible. We have large facilities for manufacturing all kinds of

Bee-Keepers' Supplies,

And will serve our customers as quickly as possible.

Falcon Sections are the Finest Made.

1899 Catalog ready Feb. 1. Copy of the AMERICAN BEE-KEEPER 20 pages free. Address

24 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 24 cents a pound—CASH—upon its receipt.

Now, if you want the money PROMPTLY, send us your Beeswax. Impure wax not taken at any price. Address as follows, very plainly,

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

Why Not Just Double

The List of Subscribers to the Old American Bee Journal?

We really believe that if ALL the present readers of the American Bee Journal were so inclined, they could help to double its regular list of subscribers before August 1, 1899 or during the next 5 or 6 weeks. We do not find any fault with what our subscribers have done in the past toward increasing the list of Bee Journal readers for they have done nobly but why couldn't the doubling of the list be accomplished within the next month? We surely think it could be done, and in order that it may be easier for those who help in it, we will make a **SPECIAL NEW SUBSCRIPTION OFFER**, and also pay all who will aid in securing new subscribers. Here is the offer:

Six Months for 40 Cents to a New Subscriber....

Yes, we will send the American Bee Journal **EVERY WEEK** from July 1, 1899, to Jan. 1, 1900 26 numbers for only 40 cents, to a **NEW** subscriber. In addition to this we will send to the present regular subscribers, for the work of getting new 6-months' readers, their choice of the premiums mentioned below, but no premium will also be given to any new subscriber on these offers, under any circumstance:

For Sending 1 New 40-cent Subscriber
 Your choice of one of the following list:

- Poultry for Market.
- Our Poultry Doctor.
- Capons and Caponizing.
- Foul Brood—Kohmke and Cheshire.
- 10 copies York's Honey Almanac.

For Sending 2 New 40-cent Subscribers
 Your choice of one of the following list:

- Dr. Howard on Foul Brood.
- Monette Queen-Clipping Device.
- Bienen-Kultur (German) by T. G. Newman.
- Dr. Tinker's Bee-Keeping for Profit.
- Pierce's Winter Problem in Bee-Keeping.
- Bees and Honey (160 pages, paper) by Newman.
- 20 copies York's Honey Almanac.

For Sending 3 New 40-cent Subscribers
 Your choice of one of the following list:

- Bees and Honey (160 pages, cloth) by Newman.
- Bee-Keeping for Beginners, by Dr. J. P. H. Brown.
- Bienenzucht und Honiggewinnung (German) by J. F. Eggers.
- Advanced Bee-Culture, by W. Z. Hutchinson.
- 30 copies York's Honey Almanac.

For Sending 5 New 40-cent Subscribers
 Doolittle's Scientific Queen-Rearing.

For Sending 6 New 40-cent Subscribers
 Prof. Cook's Bee-Keeper's Guide.

NOW FOR A GRAND PUSH FOR NEW SUBSCRIBERS!

It seems to us that with the above low rate to new subscribers, and also the premiums offered, we should get such a landslide of new subscriptions as will make us sweat to care for them during the next few weeks without any help from the hot weather. WE are ready now to enter the new names and mail the premiums. Are YOU ready to go out and get them, and then send them in?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

CONTRIBUTED ARTICLES

Home-Made Comb Foundation—How it is Done.

BY ADRIAN GETAZ.

LAST winter I found myself with about a hundred pounds of wax on hand, of rather inferior quality, that had accumulated little by little. I also needed some foundation for brood-chamber purposes.

Selling wax at some 18 or 20 cents a pound and buying foundation at twice or three times that price did not seem to me a very promising business. On the other hand, buying a \$30 mill to save \$20 on the foundation business wasn't very much better.

Under such circumstances I thought of the once famous plaster molds, and proceeded to make a set. The directions are as follows:

Make a frame of wood the size of the foundation wanted. Lay on a flat surface a sheet of foundation as a pattern, put the frame on it, and pour plaster paste in it. This makes one side of the mold. When the plaster is set, turn it over, put another frame on it (leaving the foundation), and pour in another batch of plaster, making thus the other side of the mold. Unite the two frames by a couple of hinges on one side, and you have a mold in the form of a book.

To use it, open the "book," wet both sides with warm water, pour melted wax on one side, and shut down the other side on it. In a half minute or so open the book and take off the sheet. Such are the directions given.

In the first place it is necessary to rub the plaster paste into the foundation sheet carefully, otherwise bubbles of air will remain in the cavities of the foundation and spoil the shape of the mold.

It is better to join the two frames by hinges before doing any casting, so as to insure exact correspondence of the two faces. Better use brass hinges and brass screws to avoid rust. Have the screws long enough to go deep in the plaster, so it will hold better. A few nails in the frame sticking inside and holding the plaster will also help the strength of the apparatus.

Thus armed I proceeded. The first trouble I got into was the impossibility of pulling, or rather peeling, out the sheets without tearing them up. This is due to the fact that I used for a pattern a Root sheet of foundation with deep walls. Some other make with little or no side walls should be used, if the melted-wax plan is to be followed.

I then tried the sheeted-wax plan, that is, making wax sheets and pressing them in the "book," or rather the mold. Simply shutting the book is not sufficient, so I put in the sheet, shut the "book," and put it in a press, and prest sufficiently to give the sheet a good impression.

In pressing a sheet, unless a very strong pressure is used, the wax will not be forced very deep in the depressions forming the wide-walls, so I had no trouble in taking out the sheet. But the trouble was, that the plaster is an entirely too weak material to stand any pressure at all. So I began to study about finding a substitute.

My experience in the building and contracting business enabled me to decide at once that the Portland cement was "the very thing wanted." The mold is to be made as with the plaster, only the "paste" must be thicker—about the consistency of the mortar used by brick-masons. After the first side is filled, wait a day before filling the other, as the Portland cement sets very slowly. There is, however, quite a difference between the different brands in that respect. Then fill the other side, keep the mold wet for about a week or ten days, and then open it. You will find that the wax adheres to the molds. Put the mold in a warm place, so as to soften the wax, and force it open, but be sure that the wax is not melted and absorbed by the cement. There may be some trouble in taking the wax out. The mold is now hard enough to use, but if kept wet, it will still harden slowly during several months, and eventually be as hard as the very best quality of stone, and practically indestructible. The cements of the Rosendale, Black Diamond, and similar brands set and harden much quicker than the Portlands, but their ultimate strength and hardness is much less.

The mold and press could be easily combined in one apparatus, and much easier to handle than the way I had them. I would, however, retain the "book" form for the mold, as it insures an exact correspondence of the two faces.

Making foundation by the press process requires sheets of uniform thickness. In the roll process the inequalities of thickness are "laminated out" by the rolling, but no such thing takes place in the press.

Dipping the boards endwise in the wax is unsatisfactory, as the wax runs down and hardens in streaks.

Use a dipping-board with a handle on one side. (See Fig. 1.) I simply lay it on the melted wax in a slightly rocking manner, so as to avoid having bubbles of air be-

Fig. 1.

Fig. 2.

tween the board and the wax, then take it out and turn over. (See Fig. 2.) This causes the melted wax to spread over the board uniformly, and insures a very regular sheet. As soon as the wax loses its transparency, I plunge the dipping-board and wax into a vat of warmer water, which causes the sheet to come off of itself, and with less danger of cracking than by cooling off in the comparatively cold air.

In cooling off, the wax-sheet shrinks, and unless it can, so to speak, glide on the dipping-board, it will crack. When I first began I noticed that the cracking was invariably in a certain place, and in a certain direction, showing clearly that it was due to a defect in the wood. It is necessary to have the dipping-board made of fine-grained, perfect wood kept as smooth as possible.

I have not yet tried any substitute for wood. Whatever material may be used should be porous, so as to retain water (otherwise the sheets would not come off), and be as smooth as possible so as to permit the contraction that takes place when the wax cools off.

The wax can be melted in a vessel, or rather a tank of tin; this to be placed in another of sheet iron containing

Fig. 3.

water kept boiling all the time. I find that a little water in the vessel containing the wax helps to melt it more rapidly.

A tank or vat can be made of tin or sheet-iron without soldering or riveting, by folding the corners as shown in Fig. 3, but it would be difficult to describe the process.

SECTION SUPPORTS ON FENCE SEPARATORS.

Somebody spoke about nailing buttons (I suppose square pieces) of tin under the fence separators to support the sections in the supers, and dispense with T tins and other contrivances to support the sections. I wish to say that the ordinary tin is too weak, but the galvanized iron, 26 gauge, used on buildings for gutters and cornices, would be strong and stiff enough for the purpose. Scraps of it can be procured at no cost at any tinner's shop where such work is done. There is some danger when nailing in small pieces of wood of splitting the piece into which the nails are driven. This can be prevented by clamping the pieces in a vise while the nailing is done. Knox Co., Tenn.

The Premiums offered on page 401 are well worth working for. Look at them.

The Nectar in Flower-Cups—Pure Italians.

BY A. NORTON.

HARDLY think that any, or at most many, will attach much weight or importance to the idea that nectar in flower-cups varies in strength and quality according to layers in the same blossom, and that different lengths of tongue in different bees will make a resulting difference in the character of honey they might gather from the same flowers. This has nothing to do with the question of the ability of bees with longer tongues to gather honey from species of flowers where those with shorter tongues could not reach it. In this latter case the longer-tongued bees would gather *more* honey and *better*, providing the flowers in question produced a better kind.

But the other idea seems to me very far-fetched, and without any disrespect toward any who have brought it forward, it seems to me hardly worthy of serious discussion. But I wish to look it over briefly.

In the first place, the nectar as secreted originally by the flower is a uniform product—it is already a sweetened liquid, not clear water and solid or thickened sweet. Hence it is exuded into the flower-cup as a homogeneous mass all alike. In the second place, it is not composed of incompatible substances, as, for example, the cream and the water in milk, or as the lime and water in whitewash, or as paint in oil. On the contrary, the substances have the greatest affinity for each other (I do not mean chemical affinity, but molecular attraction or affinity).

Hence, the cream in milk is in a state of suspension; and, being lighter than water, rises to the top; while the lime in whitewash and the paint in oil are also merely suspended therein, but being heavier tend to settle to the bottom. But the sweet in nectar is in a state of solution, and is held everywhere dispersed thru the water by molecular attraction. If you put solid sugar at the bottom of a glass of water and give it time enough, the sugar will gradually be dissolved and carried thruout the water; this will occur even if the sugar be tied up in a bladder or other porous membrane. And there will in time be no heavier or sweeter layer at the bottom, *unless the sugar be in excess of the saturation point, which is not the case in the thin nectar of flowers.* Hence the *tendency* of sweet in water is toward diffusion, and not toward accretion, until the saturation point is reached. The same is true of salt and other soluble substances. Did any one ever hear it claimed that sap was sweeter in the bottom of the pail? Was it ever claimed that the honey was sweeter in the lower portions of the cells in the comb, or, if extracted, in the bottom of the can? This would be more likely on account of the greater proportion of sweet in solution than in the case of nectar.

Mineral springs are constantly depositing lime, silica, etc., in all conditions of the water, and wherever the water flows from them, for these substances are only in suspension. But the inland lakes of California and Nevada do not deposit salt, soda and borax until evaporated down to the saturation point; and, as the saturation points of these substances differ, they are not all deposited together, but in more or less defined layers, so that in dry lake-beds these deposits are reached in regular succession by digging.

And, finally, if the sweet of nectar would settle (which it does not) the largest drop of honey produced by any flower would be too small for any difference to be noticed.

QUESTION FOR MR. DOOLITTLE ON PURE ITALIANS.

In closing I wish to ask a question of Mr. Doolittle, who I think is about right. (See page 306.) But if the Italian bee is not a pure race, and if this is shown by the increase amount of yellow that has been bred into some strains, then should not some pure stock exist with still more yellow than the yellowest bred Italians? All crosses are *between* the two pure types that produce them. Where is any race found of nearly pure yellow bees? And, especially, where are such near enough to Italy to have served the purpose of crossing with blacks to produce the common Italian bee? Monterey Co., Calif.

Making Increase by Dividing—Feeding Bees.

BY C. P. DADANT.

IN a previous article I stated that it was our method to take the increase in bees, when any is wanted, from colonies that are not expected to store much surplus. Our reason for doing this is that we have always noticed—and all who have had extensive experience in the apiaary will

sustain us in this—that it is the strongest and best colonies from which the real honey crop may be expected. If such colonies may be induced to work freely in the surplus instead of swarming, and we succeed in this by our methods in most cases, these colonies may be depended upon for a crop far in excess of what the colonies under average would yield. The prolificness of the queen may not be the sole cause of the difference. We believe that the greatest cause of the difference in yield is the earliness or lateness of the breeding; the early colonies having the bulk of their bees ready for the harvest, while the late ones have them ready too late, as mentioned by me in a previous article.

But aside from these causes, it is probable also that there is a difference between colonies in the activity of their bees as there is in men, some being more industrious or better managers than others. For this reason, altho we want the increase from the late and comparatively inferior colonies, we must not get our breed from them, for it is also of the utmost importance that our queens should be of the very best quality, that is, bred from the most prolific mothers, and of a race of active workers. In a word, we must do with our bees, as much as in our power, what we do with our horses, our cows, our chickens, and our pigs—breed from the best, the gentlest, the most serviceable all around.

To do this and yet keep our best colonies at work producing honey, all that is necessary is to rear our queens from select colonies, taking from them, or rather exchanging from them, as much brood as is necessary for our purpose.

It is not in the scope of this article to give instructions on the rearing of queens or on the making of nuclei, suffice it to say that we must rear, in nuclei or otherwise, as many young queens as our swarms will need. These queens may be introduced while yet in the cell to the divided colonies.

When we say that we take our increase from inferior colonies, we do not wish it understood that we take it from weak colonies. A colony which has not filled most of its combs with brood by the middle of June, is not to be expected to furnish any increase. What we mean to say is, that when the harvest has begun fairly, we take the increase from those colonies which, altho apparently strong, do not work in the supers. The weak colonies would better be let alone, and if their queens are at fault, perhaps they would better be replaced, and it is quite likely that some of our young artificial swarms will soon prove superior to such colonies.

We proceed as follows: Selecting the colony which is to furnish us the larvae for our young queens, we exchange a number of its brood-combs, those containing young brood, for the same number of brood-combs of an inferior colony, without the bees, taking care to leave in the latter hive only such brood as has been furnished by the selected colony, for if we left them any of their own brood, they might rear queens from this perhaps in preference to the other. As a matter of course, the queen of this hive is removed, either to be killed or given to a queenless colony, or exchanged for a still poorer queen in another hive.

The now queenless colony goes to building queen-cells from this selected brood. On the ninth day after the operation we are ready to make as many swarms as there are queen-cells but one, since one is needed for the colony that reared them.

We now go to our colonies from which we desire the increase, find the queen of each and remove her to a new stand with half of the brood-combs, more or less, according to circumstances, and a goodly number of young bees, enough at least to keep the brood warm. It must be remembered that as this colony, or rather this swarm, gets none of the old bees, it needs a rather larger number of young bees than would appear necessary in order to take care of the brood.

On the tenth day, or the day following this operation, we give each of our queenless divisions a queen-cell, grafted on the combs in the usual way. These hives should as much as possible be supplied with empty comb, or full sheets of foundation, as their bees will build nothing but drone-comb until the young queen is laying, which will require from 6 to 15 days. This is important to remember. On the other hand, the hive containing the queen may be depended upon to build mainly worker-comb in its empty frames, as their numbers are diminished, and there is but little inducement to the building of drone-comb in any other than a queenless or a wealthy colony. The queenless colony builds drone-comb because there is an instinctive feeling that drones are needed to fertilize the young queen when hatch, and the wealthy colony builds drone-comb be-

cause it is more spacious, and requires less labor for the same amount of honey than worker-comb.

Should the colonies from which the increase is taken prove rather too weak to follow exactly the above methods, one swarm may be made from two colonies, by taking the queen and only one or two combs of brood from one hive and placing the swarm thus made on the stand of another colony which is removed to a new position. We have used the same colony three times over to furnish bees to new swarms, by removing it at intervals of 10 to 20 days, and placing a new swarm on its stand.

By following the methods above given, varying the proportions of bees or brood taken with each swarm to suit the circumstances, one may secure quite an increase from colonies that would have yielded but little, and at the same time one retains the best colonies for honey-production. We have always found this method the most profitable, and much prefer an artificial swarm, carefully made and properly managed, to the swarms secured by natural swarming.

As a matter of course, if your best colonies swarm in spite of your endeavors to prevent them and to keep them at work, you will have good swarms, but it will be at the expense of the honey harvest.

WILL IT PAY TO FEED THE BEES?

I have received the following questions, which I will answer here:

I have 27 colonies in good hives, which wintered well, and I have had 10 big young swarms already. But the bees have no honey in their hives. I don't think they have a pound. They are beginning to kill the drones, which shows that they don't get honey enough to feed the brood. Will it pay to feed them? I have fed \$10 worth of sugar already. We have very little white clover, but the basswood is full of buds, and it will be about three weeks until it begins to bloom; but the ground is full of young white clover all over. Will this young clover that came up from the seed this spring yield a crop of honey next fall, or will it not produce until next year? We have had a very wet spring. T. L.

ANSWER. The experience of Mr. L. has been ours many times. We have seen a number of seasons when the crop failed till the month of June was far advanced, but we have always fed whenever it was needed, and have always been repaid for the trouble and expense. We will confess that in a number of instances we came too late, and even lost colonies in out-apiaries from sheer starvation, when the fields and meadows were white with bloom. Our experience is that the very best seasons often commence in this way, for the excess of rain is more detrimental than any other cause to the immediate production of honey. But the excess of rain also produces an excess of vegetation, and sooner or later in the season a lull in the rainfall gives the flowers a chance and the honey flows abundantly.

There are drawbacks in all lines of business, in all branches of farming, and ours is not exempt. It is the man who perseveres, who "stays with it," that wins the laurels. The wet season will produce an amount of bloom which could not be expected in a dry one, and just as soon as circumstances are right the harvest will begin. In the season of 1875-24 years ago—we experienced such a season as the present one. We fed all thru the months of June and July, and still the rain poured. In August colonies deserted their hives, and I saw a sight that I have not seen since—a swarm hanging to a limb and the bees dropping from the cluster to the ground from inanition. But the flood came to an end in September, and in the first two weeks of that month we harvested more than ten times the amount expended during the season.

In regard to the question as to the young white clover, I cannot make a favorable answer. I have never seen much honey harvested from young clover, even if it bloomed the first year of its growth. It is only during the second year that much may be expected from it. We have great hopes here yet of a clover harvest for this year, altho we have had too much rain. There is an abundance of bloom, and if the weather gets favorable we will surely harvest enough to pay us all for our trouble. Hancock Co., Ill.

Dead Bees on the Hive Bottom-Boards.

BY G. M. DOOLITTLE.

GOING past a would-be bee-keeper a few days ago, I was called in to see why some of his colonies did not work as strongly as others in the yard. After looking at the entrances of the hives for a moment, noting that some were working strongly while others were doing but little, I asked if the hives had been opened to see what was the trouble.

"No," was the reply I received. I knew this man kept sheep, and so I said, "How are your sheep getting on this spring?"

"Oh, first rate," was the reply.

"How do you know the sheep are doing well?" I asked.

"Why, how does any one know anything? I have foddered the sheep three times a day all the winter and spring, and been with them lots beside, even getting up many times cold nights to look after the newly-born lambs that they need not become chilled and die. And being thus familiar with them, why should I not know when they are prospering?"

"Very well," I said. "How many times have you 'foddered' the bees this spring?"

"Not a once," was the reply. "Didn't suppose they needed foddering."

"Have you been up any during cold nights to see that the newly-born bees did not chill, or paid any attention to the hives to see that the bees were made as comfortable as possible, either night or day?"

"No, I had to look after the sheep so much that I had no time left; nor did I suppose that bees needed caring for like sheep; and I am sure that it would not pay me to spend time on them as I do on the sheep."

"How many sheep had you last year?"

"About 60."

"How much did you receive from them for all your work, 'foddering' feed, etc., expended on them during 1898?"

According to my book, not far from \$325."

"A pretty good showing, but when I tell you that last year from 30 colonies of bees at my out-apiary I sold comb honey to the amount of \$348.28 you will see that the proper amount of time spent on the bees pays fully double per colony that you get from a sheep, with only a tithe of the work you spent, and that also without any cost for 'fodder.' But let's look into this colony of bees which do not seem to be flying much."

I had noticed that where the bees were flying the strongest there was quite a number of dead bees out on the ground about the entrance to the hives, but with those not flying as strong there were less dead bees, and what there were showed by their old looks that they had been hauled out during the winter. I had also noted that his hives had loose bottom-boards, from some empty ones which were piled up, so stepping to the hive designated I laid a bottom-board down beside it and lifted it over from its own stand to the one I had put down. By thus doing I exposed almost a sickening sight from the dead bees that were under the hive, all moldy in places, and in others all wet and fairly rotten, with worms crawling and working amongst the rotting bees, while the stench was horrid when this putrefying mass was disturbed.

Looking up at the man, I said, "How do you suppose that your sheep and lambs would thrive if you neglected them as shamefully as you have these bees?"

"Not much, I guess," he said, his face showing shame and confusion.

I now set the hive back again, keeping under it the dry, clean bottom-board I had set it on, and proceeded to open the hive. There was brood in three combs to the amount of about one frame full, with only about bees enough to well cover the brood, which showed that the little colony was doing its level best under such adverse circumstances, for between many of the combs either side of where the brood was, the dead bees came well up between the combs. I looked at two other hives, finding them in somewhat similar shape, tho none quite so bad as the first, fixing those look at in good shape by seeing that they had at least 10 pounds of honey, the combs free from dead bees, where such were matted together, and the top of the hive made snug and warm, telling him to go thru the rest in a similar way.

When I continued on my way, I asked myself, "Is it any wonder that so many tell us that bee-keeping does not pay?" I have often wondered that the idea has so fully obtained with nine out of ten of those who start in bee-keeping, that all they have to do is to get some bees, by finding a swarm or buying a few colonies, and provide a place for them to stand, after which a profit will accrue to them by hiving swarms and putting on and taking off sections. And when profit does not accrue, and their bees die from neglect, we are sure to be told, "Bees do not pay." Yet these very persons will work faithfully, year in and year out, caring for, feeding, grooming, etc., their hogs, sheep, cows and horses, when a much less amount of labor, wisely directed, spent on the bees, would yield a greater profit.

And the most wise of all wisely-directed labor, which can be spent on the bees, is to see that the dead bees are removed from the bottom-boards of the hives in the early spring of the year. With movable bottom-boards this is very easily done by putting a clean bottom-board on the stand and setting the hive on it, after which the dead bees are swept off from the one which was under the hive all winter, the board being cleansed with water if needed, when it is ready to be put on the stand of the next to set that hive on. And where the bottom-board is not only movable, but reversible, the work is still more simplified, for in turning the deep side down, which was up during the winter, the dead bees mainly fall off, and what adhere can do no harm, as they are under out of the way, and will fall off themselves before you wish to use the deep side again for the next winter. But with hives having the bottom-boards nailed fast, the work is greater, but even then it should *never* be neglected. A clean hive should be placed on the stand, and the frames from the hive in which the bees have wintered be set over into this clean hive, when the now vacated hive should be thoroly cleaned of all dead bees, dirt and filth, when it is ready for the next colony, and so on thruout the apiary.

In all the work done in the apiary, I doubt whether there is any that pays as well as the removing of the dead bees from the bottoms of the hive, for bees can prosper little better with a lot of their dead companions underneath their brood-nest than could we with several corpses in the cellar under our dwellings. — Progressive Bee-Keeper.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

How Often to Examine Hives.

I would like to know how often bee-keepers examine their hives. Mine get fast in spite of me. VA.

ANSWER.—Some say they don't examine them more than once in a year or two, but probably they are quite exceptional. Others examine them two or three times in a season, and many once a week. If you mean that the frames are stuck fast with propolis when you say "mine get fast in spite of me," you will probably find that you will always have trouble with propolis. But the trouble will be much less if you have such frames and rabbets that the point of contact will be very small. The trouble will also be less with even the worst kind of frames if you carefully scrape out all bee-glue once a year.

Swarms Deserting the Hive Combs Wrapt in Tarded Paper.

1. Is there anything to be done to keep a swarm of bees in the hive? I hived my new swarms last year in 10-frame hives without foundation, but most of them went away, after staying about an hour. This year I hived them in the same kind of hives with foundation, but I had the foundation wrapt in tar paper for a couple of weeks before I put it into the hives, in order to keep foul brood out, but my bees didn't stay; some of them did not want to go into the hives.

2. Had the smell of tar any effect on the bees, or do they hate it, and will it keep foul brood out of a colony? My bees are all diseased with foul brood, and almost every-body else's bees have the same trouble. MRS. S. S.

ANSWERS.—1. In probably the great majority of cases a swarm deserts a hive because it is too close and hot. If the hive is clean, and if it is in a cool, shady place, with plenty of ventilation, the swarm is likely to remain. If the hive must remain in a hot place, it may be a good plan for a day or two to keep it sprinkled with water during the

hottest part of the day. Be sure to have the hive well ventilated by raising up, and for a day or two it may be well to have the cover slightly open or raised, so the air can circulate freely thru.

2. Unless the smell of tar is very strong I hardly think the bees will mind it, but I may be mistaken. I have read of Australian bee-keepers wrapping foundation in tarred paper before giving it to swarms, and it was claimed that it prevented foul brood, but I don't know whether it has been tried in this country.

Likely Afflicted with Paralysis.

I have a colony of bees in which there are a number of small, black, glistening bees, and other bees seem to be trying to kill them off. The colony is in a prosperous condition, but I can't understand where the black bees come from. PENN.

ANSWER.—Very likely they are afflicted with paralysis, and as far north as Pennsylvania you need pay no attention to it, for the disease will probably disappear after a little while of itself. So far there seems to be no reliable remedy for it.

Keeping Roaches, Ants, Etc., Out of Hives.

I want to find out how to keep bugs out of hives, such as roaches, ants, mice, bee-lice, etc. N. MEX.

ANSWER.—The best way to keep roaches, ants and mice out of hives is to have no retreat in the hive to shelter them. Have your hive so arranged that bees can get to any part of it, and the bees will keep out the intruders. An ant or a roach can get thru a crack that will not allow a bee to pass, and in hives that have a quilt over the frames they have a safe place for a nest into which the bee cannot come, that is, between the quilt and the hive-cover. But if you use a plain board cover, there is no such retreat. The bee-louse (*braula coeca*) is troublesome in other lands, but I never heard of it being troublesome in this country.

A Quartet of Questions.

1. I want some colonies to build all the comb they can from frames with foundation, and I don't care for surplus from those colonies. Which way would you advise for best results?

2. Will bees cross a bay (1½ miles across) as readily as if it was land?

3. At what age is a queen most prolific?

4. How many Hoffman frames should a good queen have filled with brood by this time? I mean everything favorable for her laying to her full capacity. My best queen has 17 frames well filled in three stories. WASH.

ANSWERS.—1. I don't know. Perhaps something like this: Get the colony strong, filling as many frames as possible in two stories. Take out about half the combs with brood, giving frames of foundation in place of the brood taken away, and putting the foundation in the central part. Put the brood taken away in an upper story, with excluder between it and the two lower stories. Repeat the process every week or so, always taking away the oldest brood present.

2. I think not. But once having found their way across, they would go across the water that distance for stores as readily as if it was dry land.

3. Probably in her second year.

4. I should say she was doing good work if she filled 12 or 14. Your queen must be a fine layer.

Bees Affected with Foul Brood Extracting.

1. I have kept bees over three years, and this spring I was especially interested in them. I have spent lots of money for them by buying supplies, bee-books and bee-papers. I was with the bees every day from five to six times, from about the beginning of April. I have 15 colonies, ten in 10-frame hives, and five in 8-frame hives. Eight colonies in the 10-frame hives are pure Italians, and the other two colonies in the other two 10-frame hives are pure blacks; the 5 colonies in the 8-frame hives are hybrids. Every colony came thru the winter very nicely, and built up fast. The beginning of May they started to work in

the supers, and May 14 the first swarm issued, and up to June 6 I had the sixth swarm.

Just a few days ago one of the black colonies was stopping work in the supers, so I thought I would see what was the cause. As I opened the hive I found that almost every comb had more or less foul brood in it, and as I opened all the other hives the same day, I found about half of the colonies had some foul brood, but only on two or three combs. (It may be that it has spread all thru the colonies now.) I really can't tell how sorry I am. I can almost say I love my bees, but when I found foul brood in some of the hives I almost felt like crying. I have neither opened nor handled any of the diseased colonies since, for fear some of their bees might give the disease to the other colonies. I don't like to destroy the diseased colonies, if possible I would like to save them. How can I get rid of the disease without destroying any of the colonies, at least those which are not affected so badly? I have heard of spraying the combs. What do they spray with, and what kind of tool is used?

2. I expect to buy an extractor; what kind would you advise me to get? I mean to increase my colonies to about 80. I have some two-story hives for extracting, and in the fall I mean to extract from the brood-chamber, so I will always keep nothing else but Langstroth size frames.

NEW YORK.

ANSWERS.—1. A good deal has been said one time and another about using naphthol beta or some other drug to cure foul brood, but hardly any one in this country nowadays thinks it advisable to trust to anything of the kind. It does seem hard to destroy nice combs, but it may be the cheapest thing in the long run.

2. A 2-frame extractor, such as the Cowan, would probably answer your purpose nicely.

Young Queen Swarming the First Year.

If a young queen is given to a nucleus in April, before swarming, will she swarm the first year?

SUBSCRIBER.

ANSWER.—Quite likely she will if the colony becomes strong, and room is limited, but she is not so likely to swarm as an older queen.

Colony Suffering from Laying Workers.

I have a colony of bees that has laying workers. Will it do any good to buy a queen and give to them? I gave them a frame of eggs and brood last week, and find that they started several queen-cells, but in each one there are four or five eggs to-day, so I think it is a waste of time to give them any more—only on your advice will I do so.

CITYMAN.

ANSWER.—It probably won't pay to fuss with them, for in most cases the best thing is to break up such a colony and give their frames to other colonies. If you had a queen-cell just ready to hatch, or, better still, a young queen that was just hatched, it might pay to give to them. If you unite them with another colony or colonies, you can afterward draw brood and bees from those colonies and start a nucleus that will be ahead of what you would have had from this colony of laying workers.

Bees Affected Perhaps Not Foul Brood.

About 30 days ago I was forming new colonies by cutting out queen-cells from natural swarms, grafting in frames of brood, placing in new hives, and shaking off some young bees from other hives, or changing places with other hives, etc. I found one colony with brood badly scattered, with sunken caps, with nearly all the sealed brood dead, but I had shaken off two frames of brood before I noticed the condition of the brood. I had given the new colony a cap cell already. I promptly closed both hives, went to my library and read up all I could find on foul brood. (I have Langstroth and A B C), and after reading all in them on the subject, I lookt over all back numbers of the Bee Journal that had anything on foul brood, and from all the information I could get I was not satisfied whether this was really foul brood or not. I then ordered Dr. Howard's book on foul brood, and after reading this book carefully I came to the conclusion that my case was the same trouble as the one Dr. Howard describes on pages 12 and 13 in his book, and not foul brood. But the queen that hatched from the

cell given to the above-mentioned colony was lost in mating, and I gave this colony a frame of unsealed brood to rear a queen. I examined this colony this morning, and I found dead brood. I cut in one of the queen-cells and found a sick larva. The cells are all capt now, and I find another colony (next door neighbor) has dead brood. I burned the old colony, hive and contents on the same day, or rather night, that I made the discovery of dead brood. Now, the looks of the combs were just like the cut in Langstroth's book, page 448—all, or nearly all, brood dead that is sealed, but none seems to be affected that is not sealed. The dead brood has no bad smell, and is not ropy, and none so far that I have found settles down in the lower side of the cell, but is still in perfect shape. The unsealed brood, so far as I can tell, is perfectly healthy. Do you think this is foul brood? I will be glad to furnish some samples for a microscopist. How shall I prepare it for the mail?

GEORGIA.

ANSWER.—According to your description it hardly seems like foul brood, but it would be the part of wisdom to consult some one better informed as to foul brood, say Dr. Wm. R. Howard, Fort Worth, Tex., or Wm. McEvoy, Woodburn, Ontario, Canada. A good way to send the brood by mail is to send it in a tin box such as is used for seedlitz powders, or a plain square tin box with cover that any tinner would make for you. Of course paper would be wrapt around the tin box.

Hive with Jumbled-Up Combs.

I bought a colony of bees the hive of which had not been opened for three years. I got it home and opened it, and found all the frames (8 Langstroth) one solid mass. I cut one out, but the comb fell to pieces. I then closed the hive up. As I wish to get a swarm or two from the colony by dividing or otherwise, will you please tell me what is the best thing to do?

N. B.

ANSWER.—If I understand you correctly, the frames are so filled with combs built crosswise that they cannot be taken out. The best thing is to let them swarm naturally, and there is not much trouble but what a good colony in an 8-frame hive will do so. If you think there is any danger they will not swarm, you might make the matter a little more sure by refraining to give them surplus room. It may not be a bad plan to continue a colony in the same hive, depending on a swarm from them each year, and depending on the swarm for surplus, putting the swarm on the stand of the old colony, and putting the old colony close beside the swarm, then a week later moving the old colony to a new stand. That will make the swarm strong for surplus honey, and it will weaken the old colony so it will not swarm the second time. But if you care more for increase than for honey, then put the swarm on a new stand, leaving the old hive on its own stand.

Several Questions—Locust vs. Basswood, Etc.

I find at this time, after having a large prime swarm, the first thing they seem to be doing is to build a queen-cell or cells. I use 8-frame dovetailed hives, with 7 frames of straight comb which I have on hand, and one of these 7 I give them, with only a small piece of comb, or a small piece of foundation, so as to give them a place to build or deposit wax, as I believe it must be their characteristic to build some new comb. Now, is it natural for them to build queen-cells? They are laying eggs in regular form.

2. I have clipped one queen's wings, and intend to destroy her when she goes out to lead a swarm, and eight days from then destroy all queen-cells but one, to prevent further swarming. What do you think of the value of this?

3. I have one hive which is now hatching a large supply of drones. How is it best, if best, to destroy these?

4. How do you estimate the value of locust as compared with basswood for honey? I ask the last question as locust grows much more plentiful here than basswood.

I might add that where I found queen-cells started in these prime swarms I failed to find queens, as I lookt for them, but possibly I overlooked them, as they were very large swarms, and the queens very shy, owing to their being cast by the black bees.

POLAND.

ANSWERS. 1. I think it is much more common than is generally supposed for a swarm to build queen-cells. Sometimes they are built right after swarming, and sometimes later. The greater part of superseding is probably done

after swarming, and it must be remembered that in the natural order of things every laying queen is superseded.

2. It will work all right if you don't miss any cells.

3. Kill them dead before ever they get alive. Shave off their heads in the brood form, or, better still, cut out the drone-comb and put patches of worker-comb in its place.

4. I think basswood is valued as a honey-tree much more than locust. Possibly if locust came as late as basswood the case would be different. Locust is valuable for building up, even if not a drop of surplus is ever gotten from it.

Colony Troubled with Wax-Worms.

I have a colony of bees in a box-hive, and yesterday as I was going thru my bee-yard I found quite a number of young bees on the ground in front of the hive, and on the bottom-board; some of them were dead, and others were alive; I noticed the bees dragging them out. From what I can get out of the American Bee Journal I think it is the wax-worms that are making trouble with them. What is the best thing for me to do? Mo.

ANSWER.—If the trouble is from worms, you may do some good by digging the worms out of their silken galleries that they have spun. Take out a frame of brood, and you will see the galleries of the worm running along the surface of the comb. Take a wire-nail, dig out one end of the gallery, then the other, and then tear it entirely out, and you will dislodge the worm. Some say that if you hammer on the frame with something hard, like a knife-handle, the worms will crawl out and drop to the ground. I haven't had worms enough in my combs to try it. Neither will you need pay any attention to worms if you have strong colonies, especially if they are Italian. Even a weak colony of Italians will keep the worms at bay without any help on your part.

Horses Near Bees.—F. L. Thompson reports in the Progressive Bee-Keeper that V. Divinny, when working horses near bees, makes a smudge to the windward, of any convenient material, especially dry horse-manure, that will make abundance of smoke. Result, safety.

The Amount of Wax from Old Brood-Combs is a thing often inquired about. F. A. Gemmill says in the Bee-Keeper's Review that his average yield of wax from a set of eight Langstroth combs is three pounds. As he uses a press of excellent power, the probability is that this is a high average; but it is well to have something as a standard.

Honey-Dew for Winter Stores.—After experiencing a loss of 25 percent of his colonies in wintering, D. W. Heise says in Canadian Bee Journal: "My first experience of leaving honey-dew in the hives for winter stores has taught me an object lesson, and I now promise *never* to do it again." Mr. Heise, don't be rash; sometimes it is easier to make a promise than to keep it.

Empty Combs Above or Under the Brood-Nest.—When an 8-frame hive becomes crowded with brood, Dr. Miller puts a story of empty combs under, so that the queen may extend the brood-nest downward. If the empty combs are put above, it cools off too much the brood-nest. But Delos Wood says in Gleanings in Bee-Culture that he gives the empty combs above, because when the upper story is filled with brood and honey his bees are likely to swarm, no matter how much empty room below. In California there may not be the same danger from cool weather as in northern Illinois.

For Cure of Foul Brood, Henry W. Brice says in the British Bee Journal:

"No doubt disinfectants are most useful in modifying the virulence of the disease under certain conditions, but

the conclusion I am forced to is that this modifying power takes place so long as the energy of the agent exists, and on its exhaustion matters are not improved; they have been simply held in abeyance, unless a state of immunity supervenes. To summarize the treatment, my advice, tho containing little that is new, is: (a) get bees off combs and destroy the latter at once by fire; (b) keep bees confined for 24 hours (this will kill many of the badly diseased ones), rebive them in a clean hive on starters only; (c) re-queen or give hatching queen-cell in 48 hours, *i. e.*, before any eggs are hatch out that may have been laid; (d) feed daily with medicated syrup for two months at least; (e) paint old hives and supers used in connection with diseased bees as above mentioned; and (f) consign to the flames without delay all quilts, combs, frames, etc., removed from diseased colonies, and do not leave infected matter about an apiary within reach of bees."

Marketing Honey.—Some branches of production in this State have become so thoroly organized that they practically control the markets in their particular lines. Similar results should obtain among the producers of honey. As it is, a few local jobbers by concerted action are able to bear the markets on this coast, and having obtained control of the most of the output, proceed to bull the markets in the Eastern States. The result is that an article which brings the producer from 6 to 7 cents, after having the profits of the middleman and the tariffs of the transportation companies added, costs the consumer anywhere from 15 to 25 cents. The producer and consumer must be brought closer together.—H. M. Peters, in Pacific Rural Press.

The New York Honey Market.—Years ago J. E. Crane sold most of his honey in the New York market, as he relates in Gleanings in Bee-Culture, and at that time much of the honey was in 4-pound boxes, but some in 2-pound single-combs glast. On visiting the same market last winter he didn't see a 4-pound box, and scarcely a 2-pound section. The dealers said square sections had had their day, the demand being for tall sections. A section 4x5 is preferred to one 3½x5. No importance is attach to the matter of having the row of cells next to the wood sealed. The general preference is for glast sections. A case holding 25 to 30 sections is preferred to a smaller one. In some cases sections are sold by the piece. Honey in plain sections was scarcely to be found, having been pickt up by retail dealers.

Artificial Increase.—W. W. Somerford tells in Gleanings in Bee-Culture how he has increased from 7 to 50 colonies. The 7 colonies were in 2-story 10-frame dovetailed hives, with about 10 frames of brood each, some of it in the upper stories, each colony having plenty of honey. The queens were removed from the 7 colonies 11 days before dividing. One of the 7 colonies had hatching queens, and from this colony "pulled queens" were taken for some of the nuclei, the others receiving two to six queen-cells each. Each nucleus had two to four combs well covered with bees, and the entrances were closed with moss, grass, or green leaves, so that the bees could gnaw their way out in the course of two or three days. The seven nuclei, however, which occupied the parent locations, did not have their entrances closed, and to these no brood was given, only a bunch of queen-cells. When the queens were removed from the parent colonies, the best of them were taken for use in another apiary, the rest were killed.

Production of Comb and Extracted Honey.—Here is the plan of H. H. Hyde for producing both, as given in the Progressive Bee-Keeper: Say an apiary of 50 colonies in 8-frame hives, nearly all two stories, having been left thus from the previous year. Give the queen the run of both stories, push breeding, feeding if necessary. When the fast flow comes, take away one story, and fill the remaining story as much as possible with sealed brood, putting the youngest brood at the outside. Put on sections filled with foundation, also as many bait sections as are on hand. Storing will continue above, and the hatching bees will allow the queen plenty of room below, so swarming will be limited. As the flow gives away, the section-supers are gradually replaced by extracting-supers, ready for the long, slow flow. At the time the brood-combs (without bees) were taken from the 30 colonies, they were tiered up on the remaining 20 colonies, and these were kept for extracting. The cotton-bloom, beginning July 15, is extracted, and the inferior broomweed honey is left for winter and spring.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,
15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

JUNE 29, 1899.

NO. 26.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Advance in Prices all along the line seems to be the order of the day, and with the advance of lumber and nails bee-keepers' supplies are likely to have a rise. So reports Gleanings in Bee-Culture. Well, that's all right, providing the price of honey keeps proper step with the advance of other things. But will it?

Salt to Kill Grass. Editor Hutchinson, in the June Bee-Keepers' Review, says that salt sprinkled around a hive will kill the grass that is near it. It is better to thus kill the grass for two or three inches around the hive than to attempt to keep it cut. The lawn-mower cannot get near enough to cut all the grass that grows close to the hive; and to keep it pulled, or sheared off, is quite a little trouble.

The Illinois Pure-Food Legislation. In the Chicago Record we find the following paragraph respecting the Dunlap Pure-Food Bill which was past by the State legislature at its last session:

PURE-FOOD LAW'S REQUIREMENTS.

The pure-food law creates the office of State food commissioner, who, with the advice and consent of the governor, shall appoint two assistant commissioners. One of these shall be an expert in the matter of dairy products, the other a practical and analytical chemist, who shall be known as the State analyst. The commissioner also shall appoint six inspectors. It is made the duty of the food com-

missioner to enforce all laws that now exist or that may hereafter be enacted in this State regarding the production, manufacture or sale of dairy products or the adulteration of any article of food. He is given authority to prosecute violators of the pure-food laws, and the State's attorneys in all counties are required to render legal assistance when called upon to do so by the food commissioner. The law contains sections which define food adulterations and regulations regarding the branding and labeling of barrels, boxes, etc., together with the penalties for violations of any of the provisions of the act.

We find that portions of the law go into effect, while the balance of it waits until July 1, 1900. The State food commissioner is to be paid a salary of \$2,500 a year; two assistant commissioners, \$1,800 a year each, and six inspectors \$3 a day each.

The important thing is to get as commissioner a man who is absolutely fearless and unpurchasable, if the anti-adulteration laws are to be made effective. We shall be interested to know who is to be that officer. We believe all are to be appointed before July 1, so we will be able to announce them in a very short time.

Apis Dorsata Found and Lost. As previously reported, Mr. Rambo, the missionary in India, had secured at least part of a colony of *Apis dorsata*. Gleanings in Bee-Culture for June 15 reports that no queen was found with them, and all dwindled and perished. A week later another colony was found, and the whole colony successfully hived. Next day they left the hive and brood-comb and settled in the roof of the building, apparently as if to build a comb. Two mornings later they had disappeared, and Mr. Rambo pathetically says, "So I am nowhere in particular." QUES: If *Apis dorsata* won't stay in a hive in India, will they be any more likely to do so in the United States?

Food of Larval Bees.—Prof. A. J. Cook, in a note to us on the food of bee-larvæ, says this about it:

On page 276 is a note as to the character of the food of the larvæ. I think without doubt it is digested pollen. We often see pollen that even shows its nature as the brood is nearly mature. It is believed that very nearly the same food is fed by the nurse-bees to the queen and drones. Some have contended that this food was a secretion from the lower head-glands. The truth is that this secretion is the digestive liquid of the pollen. The secretion goes with the latter to the stomach, where the pollen is digested, after which it is regurgitated and fed to the brood, queen or drone, as the case may be. A. J. Cook.

Work of the National Association.—In response to the suggestion made in a recent issue of this journal, General Manager Secor sends us the following:

FOREST CITY, IOWA, June 19, 1899.

EDITOR AMERICAN BEE JOURNAL: In the last American Bee Journal, on page 376, there is something more than a gentle hint for the general manager to tell what the United States Bee-Keepers' Association is doing in the interest of bee-keepers.

I am not much of a sportsman, but if I were to go fishing for speckled brook trout I would not send a small boy ahead to throw stones in the pools if I wanted to catch any. And if I wanted to get evidence against any violator of law I wouldn't send Mrs. Grundy ahead to proclaim the object of my visit and investigations. This is why we are not publishing what we are about to do. But as this is a very large country, and as a great majority of offenders probably do not read the bee-papers, it may do no harm to say that the association has already begun the prosecution of violators of pure food laws in a certain city 8,000 miles, more or less, from Manila. We expect to spend \$300 to \$400 this year in the interest of honey-producers.

We hope to work up some test cases which, if successful, will go a long way toward stopping the fraudulent sale of glucose for honey.

Now, if anybody is interested in this line of work who is not a member of our association, he or she is hereby in-

formed that we shall need more funds than are now in sight if we continue the work.

Pure food legislation and impure food prosecutions are the lines of work laid out for especial effort this year. Other matters are also receiving attention, but the largest expenditures will probably be in the direction named.

Yours truly, EUGENE SECOR, *General Manager,*
United States Bee-Keepers' Association.

Now, the foregoing candid statement of proposed effort, and appeal for funds, ought to induce several thousand bee-keepers to forward their dollar membership fees to Mr. Secor at once. It certainly would be discouraging to get into the midst of costly prosecutions and then not have funds sufficient to push them to a finish, and to victory for the association.

There ought to be a membership of at least 1,000 in the United States Bee-Keepers' Association by the time of the Philadelphia convention Sept. 5. Why not send your dollar now to Mr. Secor, if you are not already a member? Address him thus: Hon. Eugene Secor, Forest City, Iowa. Or, if more convenient for you, send the amount to us, and we will forward it to Mr. Secor, when he will mail you a receipt therefor.

Now, please don't read this and then do nothing. Your help is needed in the work projected and that which is already begun.

Some Honey Prospects in California. Thomas G. Newman, of San Francisco, Calif., general manager of the National Bee-Keepers' Union, wrote us as follows June 17, in reference to the prospects for honey in Southern California:

The following item from the San Diego, Calif., Daily Vidette, of May 30, 1899, shows that the honey crop in Southern California is better than it was feared it would be. The drouths here are killing, and we had two years of such. This year is much better in the northern part of the State, where we had plenty of rain; but San Diego was not so blest. It is the largest county in the State. The item reads thus:

"The honey crop will not be a total failure in San Diego county, as was predicted before the late rains. It is now estimated that there will be at least a fourth of a crop, amounting in the aggregate to about 7,000 pounds, as the product of the county for this year."

THOMAS G. NEWMAN.

It seems to us there must be a big error in the above paragraph. Surely, "7,000 pounds" is not a fourth of the honey crop of San Diego county in an average year! That would make only 28,000 pounds as the total amount of an annual crop in a fair season. If it is anything like the other honey counties in Southern California, we should think that 140,000 pounds would be nearer the true amount.

Grading Comb Honey by Pictures is being pushed in Gleanings. S. A. Niver was appointed by the New York Geneva convention to prepare a set of pictures, and these appear in Gleanings. There are three grades: Fancy, No. 1 and No. 2—a set of three square sections and another set of three tall sections. Each picture is intended to represent the poorest that will be allowed in its class. The No. 2's have perhaps one-sixth of the surface unsealed. The Fancy and No. 1 sections appear not so unlike but that a novice might have difficulty in deciding their respective places. One is a little surprised to see in the tall Fancy section a dozen or more cells unsealed.

Grading by pictures is not yet an established fact, but the whole matter of grading is so complicated and difficult that anything in the line of help should be encouraged. Mr. Niver has certainly struck a good idea in selecting for each class the poorest representative of that class. Editor Root despairs of having a single system of grading that will apply to the whole country. New York bee-keepers would never be satisfied with the Colorado system that puts fancy buckwheat in second grade.

EDITOR H. E. HILL, of the American Bee-Keeper, is now in Florida, and may also go to Cuba, as he has an invitation from Dr. Viète, a resident bee-keeper, who in one season took 180 tons of extracted honey. Dr. Viète "has officiated in the Cuban army as colonel, chief-of-staff of the 1st army corps, and chief health officer." And having been the chief bee-keeper, we think he might as well be called "Chief Viète" instead of Dr. Viète.

MR. G. M. DOOLITTLE, of Onondaga Co., N. Y., writing us June 20, said:

"I am fearfully driven with work now, and have sore eyes, and a lame back to make work as uncomfortable as possible."

We regret to hear of Mr. Doolittle's temporary afflictions, and trust he may soon recover from them. It is bad enough to have to work hard in hot weather, without having ailments that make the burdens heavier.

MR. THOMAS G. NEWMAN, of San Francisco, Calif., reports in his Religio-Philosophical Journal for June 8, the visitation of an earthquake in his locality. Here is what he says about it:

"Two earthquakes shook up San Francisco and vicinity at 11:20 p.m. on June 1. Crockery, wall ornaments, and glasses were demolished in great quantities; cornices of buildings, chimneys, cap-stones and mason-work were loosened and fell to the ground; large numbers of people were alarmed, and ran into the streets in scant attire but no lives were lost, so far as we have heard. The roaring sound and flash of light accompanying it were the cause of much anxiety and foreboding at the time but it soon past away, and things resumed their usual course the quake lasting less than a minute."

When Old Earth quakes it shakes up things. The sensations felt must be anything but exhilarating in their effects. What with storms, cyclones, tornadoes, earthquakes, etc., life seems pretty uncertain. How helpless, after all, is puny man!

EDITOR HUTCHINSON, in the June Bee-Keepers' Review, writes this paragraph about the reformed spelling:

"So far I have said nothing in regard to the reformed spelling. What I have several times thought of saying, has now been said by Stenog in Gleanings in Bee-Culture. Here is what he says: 'If you will rip up the whole alphabet from A to Z, and have a precise character for every sound, as we have in shorthand, I shall be much pleased.' So long as a system is radically wrong, we gain very little by tinkering with minor results. So long as we attempt to represent 40-odd sounds by using only 26 characters, just so long will there be confusion. Bro. York gives a sample of 16th century spelling. Of course, it looks odd to us, but I doubt if our present spelling, or even the reformed spelling, would not look as odd to the 16th century folks, if they could see it, as their spelling does to us."

We hardly think it is a question whether or not certain spelling "looks odd." It is whether or not we are going to do anything to simplify the spelling for future generations. But we are almost willing to guarantee that if the whole job of reforming the spelling of the English language were done at one time, neither Stenog nor Mr. Hutchinson would be in favor of adopting it. If they are not willing to adopt a few sensible changes, naturally they would not care to undertake a bigger job. Why, if the whole thing were done at once, even publishers and editors could not handle it. It must be done by degrees if at all. No man builds a mansion in a day, but rears it little by little. So with the spelling reform, it can't be done faster than our small abilities can handle it—a few words at a time.

THE G. B. LEWIS CO'S

BEE-HIVES AND SECTIONS

Are Models of Perfection.

This is the Verdict of Thousands of Customers and the Acknowledgment of Competitors.

Our unrivaled facilities, coupled with twenty-five years of manufacturing experience, enable us to anticipate and supply every want and need of the bee-keeper, promptly and accurately.

YOU WANT THE BEST—They Cost No More.

Queen-Clipping Device Free...

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & COMPANY,
118 Michigan St., Chicago, Ill.

In the multitude of counsellors there is safety.—Prov. 11 14.

Will Tallow Prevent the Wax-Moth?

Query 04. It tallow be put in the angles of the rabbets of the supers, covers, and between and under the ends of the frames, will it prevent the wax-moth from depositing her eggs in those places, and supply the place of bee-propolis?
INDIANA.

- S. T. Pettit—I don't know.
- D. W. Heise—I don't know.
- C. Davenport—I don't know.
- E. Whitecomb—I don't know.
- Eugene Secor—I don't know.
- W. G. Larrabee—I don't know.
- Mrs. L. Harrison—I don't know.
- Emerson T. Abbott—I do not know.
- E. France—I don't know; never tried it.
- C. H. Dibbern—I don't know. Try the plan and report.
- P. H. Elwood—I should think so, but I have never tried it.
- R. C. Aikin—I do not know, but suspect it would be a failure.
- O. O. Poppleton—I have no experience in the use of tallow in hives.
- Dr. J. P. H. Brown—I have never used it for that purpose. I do not know.
- Adrian Getaz—It will; but there will be yet plenty of other places left for the eggs.
- J. E. Pond—I do not think it will. It will, however, tend to prevent the sticking

Extracted Honey Wanted

As soon as you have any good, well-ripened Extracted Honey for sale, send us a small sample, stating quantity, price expected delivered in Chicago, and how put up. Prefer it in 60-pound tin cans. Expect to be able to place car-load lots as well as smaller shipments of Extracted Honey. But don't ship us any until we order. Address,

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

Better than Ever

Am I prepared to furnish everything needed by the up-to-date bee-keeper, all goods manufactured by THE A. I. ROOT CO., ship to me in car lots, and sold at their prices. Send for illustrated, 36-page Catalog FREE.

Address, **GEO. E. HILTON,**
17A171 FREMONT, Newaygo Co., MICH.

of frames fast to the rabbets, which oft-times renders them almost immovable.

Mrs. A. J. Barber—I have never had any trouble with moth, so I have no experience.

Prof. A. J. Cook—I never tried it, but do not think so. It would not banish the moth, I am sure.

G. M. Doolittle—Keep *Italian* bees, and you will not see wax-moth worms enough to talk about.

J. M. Hambaugh—I have had no acquaintance with the anti-moth-propolis method mentioned.

J. A. Stone—I don't know, but I think it would be about as objectionable to the bees as the moths would be.

Rev. M. Mahin—I do not know. I do not believe that the moth lays eggs very often in the places named.

A. F. Brown—Try it and report. Wax-moths do not bother me, and bee-propolis I find everywhere, regardless of conditions.

Dr. A. B. Mason—It will prevent the moth depositing eggs there while it lasts, but in time the bees will remove what they can get at.

R. L. Taylor—I have my doubts about the depositing, but the tallow might destroy the eggs or the moth-worm coming from them.

Dr. C. C. Miller—I don't think the moth would lay eggs in tallow, but I don't believe it would make any difference as to worms in the hive.

E. S. Lovesy—I have never used tallow, and I never have been troubled with moth where there is a bee-space under and around the frames.

Mrs. J. M. Null—I never experimented along this line; however, moths are not a consideration only as they destroy combs which are not in use.

Chas. Dadaut & Son—What if it did prevent the moth from laying eggs in corners? There is no room for moth in a strong colony, and there is always room for them in a queenless hive.

G. W. Demaree—I have experimented only enough along this line to learn that tallow and other substances that melt at a comparative low temperature are out of place inside of the bee-hive.

Blame It on "the Heat."

"I am not feeling well to-day,
But why I cannot see;
I had some ice-cream 'cross the way
And pancakes home, for tea.
I also had some caramels,
And sugared almonds, too,
And when I met with Tommy Wells
A stick of fine Tulu;
But I was careful with each one,
For much of none I ate.
It cannot be that penny bun,
And yet the pain is great!
I had six cookies, but I've had
Six cookies oft before;
They've never left me feeling bad,
Nor the pickles—three or more.
The soda-water couldn't make
Me ill—'twas Billy's treat.
I sort of think this fearful ache
Comes wholly from the heat."
— Selected.

Northern Illinois Convention.

The bee-keepers of the eastern part of the Northern Illinois Bee-Keepers' Association held the spring meeting at the home of Oliver Taylor, in Winnebago County. The attendance was not very large, owing to the rainy day and heavy losses in wintering. The losses in this vicinity were over

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

half, and as a result the bee-keepers are feeling a little blue. The number of colonies reported in the fall were 470, and only 230 left this spring; besides, those having the heaviest losses are more apt to remain at home.

It was generally thought that the prospect for honey this year is not good, as the white clover and also Alsike is badly winter-killed. As the spring meeting is held at the home of some bee-keeper, for the purpose of seeing his methods of handling bees, and the ladies go along and take their lunch-baskets, you see it is a kind of bee-keepers' picnic, and there is not as much for a report as there would be otherwise.

Mr. and Mrs. Taylor gave us a royal reception, and we were loth to depart.

Some of the questions discsent were: Is it profitable to send South for queens in the spring for queenless colonies?

Ans.: No; double up. Is it best to double up now?

Ans.: No, not so late in the season. Don't swarms affected with dysentery in the spring have more brood in hive?

Ans.: Most of the members thought they did.

B. KENNEDY, Sec. Winnebago Co., Ill.

Report from an Old Bee-Keeper.

I am nearly 76 years old and can see and walk as well as ever. I have been used to bees all my life. I have some very fine bees. I never keep over 20 colonies thru winter. I had only one colony to die thru the winter, one robbed in spring, and one queenless, but I soon made the queenless one all right. I can always make a colony with a laying queen all right in a few days. My bees are always on the summer stands all winter. We had no honey last summer, but there is lots of white clover this year, and the bees are wild on it when there is a fine day, but we have had a very stormy time so far.

Humboldt Co., Iowa, June 20. HENRY WHITE.

Motherwort.

I send a plant specimen which I would like to know the name of. We have the sweet clover here, both white and yellow, and both in bloom, and the bees leave all and go to this plant. There is plenty of white clover here, but bees do not work on it. If what I send is a good honey-plant I will send you some of the seed.

My bees became weak in the winter, but bred up again. Macoupin Co., Ill., June 14. JOHN CRAIG.

We sent the plant specimen to our good friend, Prof. C. L. Walton, one of the high school teachers here in Chicago, who reports as follows:—EDITOR.]

The specimen plant sent for identification is commonly known as motherwort. The botanical name is Leonurus cardiaca, and belongs to the great mint family. Nearly the entire family was introduced from Europe, and is proving a boon to bee-keepers on account of the excellent quality of honey obtained from it by the bees.

C. L. WALTON.

[We might add further, that if any of our readers want to have plants or flowers named, they can mail the specimens direct to Prof. Walton, addressing him at 2863 N. Ashland Ave., Ravenswood, Chicago, Ill. He will then reply to them thru the Bee Journal.—EDITOR.]

Prospects for a Poor Season.

My bees have done just fairly well this year. I have had several swarms and but little honey. The season bids fair to be another very poor one in this locality. I am a bee-keeper of some 30 years' experience, and the most of the time a subscriber to the old American Bee Journal. I have read lots of books on bees. I well remember reading many articles from different writers

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages 16th 1899 Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.

118 Michigan St., CHICAGO, ILL.

when the Bee Journal was edited by Samuel Wagner. My old friend, James Parsons, and I, used to take it together. I was young then, but now I am 55 years old, and my old friend past away years ago. Our honey plants and trees have also past away, so much so that I can almost safely say that this part of the country that used to be a good bee-country, has been transformed, by the woodman's ax and the farmer's plow, into a very poor one. I have 53 colonies of bees in good double-walled hives. I will write an article for the Bee Journal on my experience some time. G. N. STINEBRING, Wayne Co., Ohio, June 18.

Changeable Weather.

The honey-flow was very good in May, but only ordinary in June—too wet sometimes, too awfully hot sometimes, and too cool the past week. I have some honey harvested, nice and white, and very thick.

L. A. HAMMOND.

Washington Co., Md., June 20.

No Honey-Flow to Speak of.

Bees are in fair condition. White clover is blooming, but no honey-flow to speak of.

CHAS. D. HANDEL.

Carroll Co., Ill., June 15.

Bees Booming on Clovers.

I have changed my location, coming here with 110 colonies of bees last Saturday, from Walworth County, on account of there being no bee-pasture in my home field. White clover with other clovers nearly all winter-killed there. Here the white and Alsike clovers are abundant. Bees are booming on them now. Basswood will be out in about 20 days.

I. A. TRAVIS.

Wood Co., Wis., June 20.

Bad Season for Bees.

I have had 10 swarms this year, and a very little honey. Our last frost was on June 3, and it killed everything. This is a bad season for bees.

LAWRENCE BROYLES.

Socorro Co., N. Mex., June 7.

Bees Doing Well.

I like the Bee Journal very much. It has been very dry here this spring, having scarcely any rain for two months. Bees are doing quite well.

ARTHUR L. MILLER.

Windham Co., Vt., June 19.

Backward Season.

We are having a very backward season here so far, alfalfa is just beginning to bloom, and it has been very dry for the past three months. Many that thought their bees were in good condition lost heavily thru April and May. I do not look for a very prosperous year for the bee-keepers in this section.

W. W. WHIPPLE.

Arapahoe Co., Colo., June 19.

Moth in Empty Combs—Other Notes.

I've just returned from the cellar with my darning-needle—a woman's weapon. I was not mending hose, but looking over combs in hives stored there, searching for something I did not want to find. The hives had been cleaned, and combs scraped of everything offensive, and put there to remain until there were swarms to occupy them. The eggs of the bee-moth develop very slowly in a cool cellar, and I look them over every week or 10 days, and pick out all the grubs I find, never allowing one to mature, to lay more eggs. To day I found one encased in a cocoon, and about half a dozen grubs in a score of hives. I look them over until all the moth-eggs have hatched, and as no miller can gain access to them they will be safe from their ravages during the summer.

I had expected swarms to put into these

4,000 Pounds
is the guaranteed capacity of this wagon. It is equipped with **ELECTRIC STEEL WHEELS** with stagger oval spokes, broad tires, etc. It has angle steel bounds front and rear. hives, but we've had none as yet. Some hives had their porticoes packed full of bees I noticed lately that drones were driving out, and I stooped watching for swarms.

Spider-lilies are usually favorites with the bees, but the blooming beautifully, not a bee visits them in the early morning, as of yore. I noticed lately a field of Alsike clover full of bloom, and the sun shining warm, but not a bee in sight. White clover is blooming, but I've looked in vain to see a bee working upon it.

Mrs. Stow's bees (see page 358) should have a day in court. I can bear witness to their good qualities. Whenever honey is to be gathered, they store large quantities of a fine product. It does not have to seek a market, but buyers come for it, saying, "I can't find any so nice in the city of Chicago."

In the report of the Chicago Bee-Keepers' convention, in Mrs. Stow's paper on comb honey, she says in reference to hives:

"You would probably call them out-of-date, but rather than make kindling wood of them, and give my good husband the further expense of buying more, I still use them."

Has not Mrs. Stow got her industrious workers, and money to their credit, to buy hives? I heard Mr. Stow say at one of the sessions of the Northwestern Bee-Keepers' Society, "as he had employment in the city, it was possible for his wife to keep bees!" Do their bees have justice?

MRS. L. HARRISON.

Peoria Co., Ill., June 10.

Poor Prospects for Honey.

Prospects for a honey crop are very poor here. White clover is all frozen out. I lost half of my bees, and some lost nearly all. I kept them in winter where I had them for years and always with a small loss.

THOMAS O. HINES.

Jones Co., Iowa, June 20.

Bees Can Hardly Live.

The American Bee Journal was a great help to me last year in selling my honey crop. It is very dry here, and bees can hardly get a living.

J. I. CLARK.

Addison Co., Vt., June 19.

Too Much Rain for Bees.

We have had a fine spring for bees here, and they have been busy working up to about two weeks ago, when it began to rain, and since then they have been hanging out and have not been doing much. What little clover did not freeze is coming into bloom, and the bees are working on it, but I don't think there will be enough clover in this locality to make a honey crop. But this overproduction of rain that we have had this spring has started up a good, thick crop of black-bart weeds, and lots of the low land has been too wet to plow, which will probably be sowed to buckwheat, which almost always yields nectar. Blue vervain and goldenrod are plentiful along the public highways, which are good honey-plants. I am getting sweet clover started all along the roadside, which I think is a very good honey-plant, and much healthier than rag-weeds, which I don't think yield much honey. Sweet clover will adapt itself to a variety of soils; it should be sowed two years in succession, then you will have one crop of clover coming into bloom every year.

So far I have had but one natural swarm. At present I have 65 colonies in fine condition, and expect some more swarms soon. I run my apiary for extracted honey, and think it pays best in a locality where we get just a short honey flow in the fall, like we had last fall. Of course, what is best for me may not be best for somebody else. Almost everybody buys syrup and pays 40 cents a gallon. Now if we bee-keepers can furnish them a genuine article of extracted honey at somewhere near the price they have to pay for syrup, they will always take honey. Every bee-keeper ought to try to get his

BIGGLE BOOKS

A Farm Library of unequalled value—Practical, Up-to-date, Concise and Comprehensive—Hand-somely Printed and Beautifully Illustrated.

By **JACOB BIGGLE**

No. 1—BIGGLE HORSE BOOK

All about Horses—a Common-Sense Treatise, with over 74 illustrations; a standard work. Price, 50 Cents.

EVERY BEE-KEEPER WILL APPRECIATE THIS.

A MOST WONDERFUL OPPORTUNITY.

neighbors to eat honey. All children, as a general rule, are fond of sweets, and I think honey is one of God's purest sweets. I have kept bees for eight years, and have never shipt a pound of honey. Last year I sold something over 400 gallons right at home, and I could have sold that much more. I am askt pretty nearly every day if I have some more honey to sell yet, and almost always the person will say, "When you get some honey let us know."

I think it pays better to sell honey to the neighbors, if we can realize as much out of it as we could by sending it to some distaut market.

About 25 percent of the bees died in this neighborhood. I have been out gathering up old combs where bees have died. Farmers as a general rule do not know the value of old combs, and are glad to get the hives cleaned up for the combs.

Henry Co., Ill., June 27. JACOB WIRTH.

Too Much Rain.

Bees are doing rather poorly owing to the excessive rains we are having. I have 107 colonies, which are almost without stores, and will have to be fed soon if the rainy weather continues. The sweet clover here will be in bloom in about a week.

J. F. ROSENFELD,
Cuming Co., Nebr., June 19.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bienenzucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia. A practical and condensed treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohne.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others. Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field.—Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

York's Honey Almanac is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey. A very effective helper in working up a home market for honey. Prices: A sample for a stamp; 25 copies for 40c; 50 for 60c; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, June 19.—Not any comb honey on the market except buckwheat and other dark grades. We look for new crop to start in at about 13c for best grades of white; light ambers and off white 100@12c. Extracted selling at 50@7c for ambers, and 60@8c for white, according to quality, color and package. Beeswax steady at 20@27c. R. A. BURNETT & Co.

NEW YORK, June 9.—Demand good for extracted honey, all kinds, and same finds ready sale at the following prices: Fancy, 70@75c; choice, 60@65c; fair, 55@60c; common, 50@55c per gallon. Some demand for comb honey at from 11@12c for white, and 9@10c for amber. No more demand for dark. Beeswax dull at from 25@27c per pound, according to quality. HILDRETH & SEGELKEN.

SAN FRANCISCO, June 14.—White comb, 10@10 1/2c; amber, 7 1/2@9c. Extracted, white, 7 1/2@7 3/4c; light amber, 6 1/2@7c. Beeswax, 20 1/2@27c.

Market is firm, with very little now offering, either new or old. This year's crop of California honey is light, and there is nothing to warrant anticipating low prices the current season.

KANSAS CITY, June 22.—New white No. 1 comb 15c; No. 1 amber, 14c. New white extracted, 1c; amber, 5/8c; dark, 4/8@5c. Beeswax, 20@27c. C. C. CLEMONS & Co.

CLEVELAND, March 9.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

BOSTON, May 17.—Fancy white, 12 1/2@13c; A No. 1, 11@12c; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7 1/2@8c; light amber, 6 1/2@7c. Beeswax, 27@28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded. Some, too, as stocks are a little heavier than is liked at this season of the year. BLAKE, SCOTT & LEE.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11@12c; some very poor selling at 6@7c, and dull. No more business in honey before the opening of the ensuing season. BATTERSON & Co.

OMAHA, June 2.—A few little lots of new honey from Texas have made their appearance on the market. The stock was put up by inexperienced people and only sold at moderate prices. Extracted of fairly good flavor brought 5 1/2@6c. Comb honey put up in 60-gallon cans and filled with extracted, sold at 6 1/2c. This is a most undesirable way of packing comb honey. Trade does not care for it. PEYCKE BROS.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10@11c; dark and amber, 8@9c. Extracted in fair demand without change in price. Beeswax, 25@26 1/2c.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey. M. H. HUNT

I ARISE

To say to the readers of the BEE JOURNAL that DOOLITTLE...

has concluded to sell QUEENS in their season during 1899, at the following prices:

- 1 Untested Queen \$1.00
- 6 Untested Queens... 4.50
- 12 Untested Queens 8.00
- 1 Tested Queen... 1.50
- 3 Tested Queens... 3.50
- 1 selected-tested queen 2.00
- 5 " " Queens 4.00
- Select Tested Queen, previous season's rearing, 25. Extra Selected, for breeding, the very best, \$5.00. About a pound of Bees in a 2-frame Nucleus, with any Queen, \$2.00 extra.

Circular free, giving full particulars regarding each class of Queens. Address,

G. M. DOOLITTLE,

11A20t Borodino, Onondaga Co., N. Y.

First Introduction of Honey-Bees into California —Extravagant Prices Paid for Bees and Honey.

BY J. M. HAMBAUGH.

I AM indebted to our old pioneer bee-keeper, Mr. J. S. Harbison, for the information herein given, as gleaned from his valuable work, entitled, "The Bee-Keepers' Directory," published in the year 1861. Mr. Harbison is still living, and is a highly respected citizen of a city in San Diego County.

The following letter from one of the earliest and most successful apirarists of this State, contains an authentic account of the introduction of the first bees into California, as well as the success attending their first five years' cultivation in San Jose valley :

AN OLD LETTER ON EARLY CALIFORNIA BEE-KEEPING.

SAN JOSE, Jan. 11, 1860.

MR. J. S. HARBISON—

Dear Sir:—Yours of the 26th of December propounding certain inquiries, has been received.

The first bees were imported into California in March, 1853. Mr. Shelton purchast a lot consisting of 12 colonies, of some person to me unknown, at Aspinwall. The party who left New York became disgusted with the experiment, and returned. All of the hives contained bees when landed in San Francisco, but finally dwindled down to one. They were brought to San Jose, and threw off three swarms the first season. Mr. Shelton was killed soon after his arrival, by the explosion of the ill-fated "Jenny Lind."

In December two of the colonies were sold at auction to settle up his estate, and were bought by Major James W. Patrick, at \$105 and \$110, respectively.

Mr. Wm. Buck imported the second lot in November, 1855. He left New York with 36 colonies, and saved 18. I purchast a half interest in them. I also, in the fall of 1854, bought one colony of Major Patrick, from which I had an increase of two. Mr. Buck returned East immediately, and arrived in February, 1856, with 42 colonies, of which he saved but seven. Our increase in 1856, from the 28 colonies, was 73. We also had about 400 pounds of honey in boxes, which we sold at from \$1.50 to \$2.00 per pound.

Mr. Wm. Briggs, of San Jose, brought out, in the spring of 1856, one colony, from which he had an increase of seven or eight swarms the following summer.

The above were the only importations I know of prior to the year (spring) 1857, which covers the ground of your inquiries. There are in our county at this time about 1,000 colonies.

Very respectfully, F. G. APPLETON.

Mr. Harbison then continues the account as follows :

MR. HARBISON'S EARLY EXPERIENCE.

In the fall of 1855 I sent East and had one colony of bees brought out, which arrived in Sacramento, Feb. 1, 1856. Tho most of the bees had died or escaped from the hive during the passage, enough remained to prove that by careful handling they could be imported with little loss, and that they would increase and store large quantities of honey when here. I left San Francisco, May 5, 1857, on board the ship "Golden Gate," on my way East, for the purpose of preparing a stock of bees for shipping to California. Sixty-seven colonies were prepared from my own apiaries, situated in Lawrence Co., Pa. They were taken to New York and shipt on board the steamer "Northern Light," which sailed from that port Nov. 5, bound for Aspinwall.

The bees were put on board in good order, were placed on the hurricane deck, kept well shaded and ventilated, and arrived at the latter port on the 15th of the same month, being 10 days from port to port. Having arrived at Aspinwall in the forenoon, and ascertained that no passengers or freight would be sent forward before the next morning,

Mr. J. S. Harbison.

I obtained permission to open the hives on the company's grounds, and let the bees fly during that evening, which greatly relieved them, and contributed to their health during the remainder of the voyage. The hives were closed up, and placed on board the cars, crost safely to Panama, and reshpt on board the steamer "Sonora," and sailed from that port on the evening of the 16th, bound for San Francisco, where she arrived on the evening of the 30th.

The bees had ample stores within their hives before they were started to last them thru their long journey. I neither watered nor gave them additional food during the

whole trip, except what they obtained at Aspinwall. During each day's confinement the bees labored incessantly to gain their liberty, but as soon as it was dark they always became quiet, and remained so during the night.

At San Francisco the bees were transferred from the "Sonora" to the steamer "New World," and landed in Sacramento on the morning of Dec. 2, 1857, thus terminating a journey of 5,000 miles, which was at that time the longest distance that bees had been known to be transported on one continuous voyage.

On opening the hives I found that considerable numbers of bees had died in each, and that in five all were dead. Some hives were found to contain so few bees that they were united with other weak colonies, till the number was reduced to 50. The stock was still farther reduced by sale, so that 34 colonies of bees remained on the first of April. These were increased to 120, most of which were sold in the summer and fall of that year.

Again on the steamer, Sept. 20, 1858, I returned East for the purpose of transporting another stock, which had been prepared for that purpose during the previous summer. On Dec. 6, in company with my brother, W. C. Harbison, I sailed from New York with 114 colonies, and arrived at Sacramento Jan. 1, 1859, with 103 living. Of this importation 68 were from Centralia, Ill.; the remaining 46 were from Lawrence Co., Pa.

Owing to the lateness of the season of shipping, and unfavorable weather during the first three weeks after our arrival, we were only able to save 62 out of the whole number; these, together, with six good colonies remaining from the previous year, we increased to 420 colonies, including the 68 old ones; 300 of them filled standard hives, and the remainder averaged half full. The increase was all made on the artificial principle (as laid down in this work).

Of the modes of importing bees to California, the most novel was that of Mr. J. Gridley, who brought four colonies across the plains from Michigan, placed in the rear end of a spring wagon. He arrived with them in Sacramento on Aug. 3, 1859, in good condition. His plan was to feed them, and in addition stop occasionally in the afternoon and allow the bees to fly out and work till dark, when they were closed up, to resume their journey early on the following morning. This was repeated from time to time, as they required their liberty.

J. S. HARBISON.

Mr. Harbison gives authentic records of other importations that soon followed, several instances are recorded of failures, and the introduction of *foul brood*, which made bad work for the early-day apiarists.

San Diego Co., Calif.

Foul Brood, Careless Bee-Keeping, and Other Matters.

BY MRS. EMMA WOODMANSEE.

WE read in nearly every bee-paper we pick up articles on foul brood, size of hive, wintering, amount of stores required, transferring, and a number of other things that sometimes seem monotonous; but I have just had a little experience that has taken the conceit all out of me, and in the future I am perfectly willing to read everything that can be written on any of these subjects.

A neighbor of ours bought about 100 colonies of bees late last fall without investigating them; he lost quite heavily during the winter, and was suspicious of the cause. So he called in the services of the county bee-inspector, and as we are very much interested in bees, and being desirous to learn all we could, we donned our veils and went over to watch the operations of the inspector on about 100 colonies.

We first discovered that our own bees were getting supplies from some source, but as the spring is very late here we were at a loss to know where it came from. They were also working on bran or meal, as they came in loaded and white as millers.

When we got there we found about 20 hives sitting about or piled up, from which the bees had died, and millions of bees were trying to clean up those frames, while in the barnyard was a covered bin where chop or bran had been kept, and there was probably two or three bushels of meal still there. The inspector lifted the loose cover to show us, and such a sight I never saw such a mass of squirming activity, rolling and tumbling till they were white all over, and I said, "No wonder our bees are bringing in supplies."

In looking thru this apiary, he found four colonies that

were slightly affected with foul brood, but with a good chance to scatter it over the whole neighborhood, as a good many people in this part of the city keep a few colonies in their back yards.

I am glad to say that the inspector was very careful in all his work with those infected colonies, not to leave anything that could possibly be carried off by other bees. He was also careful to impress upon us all the great importance in cleansing the hands of the operator, and all knives and other tools used about the infected colony before opening the next hive.

But I must also add right here, that I have visited the place again since then, and I find that the owner is decidedly careless, and does not even now seem to realize the fatality of the disease, as there are old combs, wax, honey, hives and frames scattered everywhere, as he said, "for the bees to clean up." Truly, we feel alarmed as we are very much attached to our bees, and dread the disease.

In regard to hives: There was a good opportunity to draw comparisons, as he has at least a dozen different sizes and makes. We noticed especially that all his colonies in 8-frame Langstroth hives were very weak, both in supplies and bees; those in 10 frames, and some in 11, were much better; and those in the very deep frames, with closed ends were very strong for the 11th of April, both in bees and honey, some having solid frames of honey and an abundance along the top-bars. Some of these strong colonies had drones hatch and crawling over the frames; these large hives contained 10 and 12 frames, at least 13 or 14 inches deep. Two colonies in sectional hives with small frames in each section were very weak.

We especially noticed that the colonies on 10 and 12 deep frames were the strongest, and had wintered best. All these colonies were in single-walled hives, and wintered on the summer stands without any protection, and even the piece of muslin, or burlap, that had been laid over the frames didn't cover more than two-thirds of the frames, and this in some of the strongest colonies. We found only two or three frames with mold on them, possibly because they had plenty of upward ventilation.

Now, after all that we have read in the American Bee Journal and other papers about the size of hive, amount of supplies, ventilation, depth of brood-frames, etc., we find that the best way to decide is to see what success people have with a number of different ones side by side. Our own bees are all in 8-frame dovetailed hives, but we have decided that a frame that will hold plenty of honey above the brood-nest is the best, and at least 10 of them.

As to ventilation, well, we have always taken great pains to give our bees plenty of packing on top, and in a sheltered place, and ours are much weaker than those of our neighbors which had no protection. Sometimes I think we can coddle our bees too much, the same as some people do their children. The children of some of our poor people are on the street half the time, bareheaded and barefooted, and half clad, yet they scarcely know what sickness is; while the children of many fond parents, with every want supplied, are invariably delicate. Surely, we will have to try to reach the happy medium, especially with our bees.

I spent a good deal of time last winter in reading bee-literature. I brought out all my old journals, then read a year's numbers that a friend gave me of 1891 and 1892; also Gleanings in Bee-Culture for 1895, Doolittle on queen-rearing, and "A B C of Bee-Culture," and I assure you it was time well spent. There are so many things we read carelessly the first time that are new when we read them again.

Arapahoe Co., Colo., April 15.

Making of Nuclei -- Open Letter to Mr. Doolittle.

BY DR. C. C. MILLER.

MR. DOOLITTLE, I have read with interest your article beginning on page 370, and I trust I shall always have the grace to receive kindly any criticism made upon any writing of mine, so long as the criticism is given in a spirit of kindness.

I think you misinterpret the question referred to on page 198. You interpret it to mean that "Iowa" meant to start nuclei, then, after queens were laying in the nuclei, to hive natural swarms in them. A careful weighing of all he says will hardly warrant such view. You hinge your interpretation upon "Iowa's" saying, "hive the new swarms." If that expression stood alone, it would be all right to view it as you do. But you must take *all* that is said, for writers are not always felicitous in their

expressions, and sometimes say something quite different from what they mean. Careful a writer as you are, you give an example of the same kind in your present article, on page 371, where you say, "The nucleus and new swarm combined should be box." Of course you do not mean that they should be put in a box, and the older readers will have no difficulty in catching your meaning.

It is by no means an uncommon thing to hear a colony called a "swarm," and I think that is the meaning "Iowa" attaches to the word when he says "hive the new swarms." The very fact that he says "new swarms" is pretty good evidence that he thought of all his colonies as swarms, and speaks of the *new* swarms in contradistinction to his 14 *old* "swarms." So I think he was referring to the nuclei or new colonies that he intended to make, and not to natural swarms that he expected to issue. One who commits the inaccuracy of saying swarm for colony might easily be expected to say "hive" when speaking of putting bees in a hive to form a nucleus. Indeed, it is not so glaring an error as to say "swarm" for "colony," and I think it would not be the first time if a man should say, "I took two frames of brood and bees and hived them in a new hive."

I said you must take *all* that is said. "Iowa" distinctly and specifically says he intends to increase "by dividing." If he forms nuclei and then puts natural swarms in with the nuclei, that would not be "by dividing," as the term is always understood. If he rears a queen in a nucleus, then puts a natural swarm in the same hive with the nucleus, he will lose a queen by the operation, and be none the better off for having formed his nucleus. It is hardly supposable that he is so lacking in intelligence as to propose anything of the kind. So it seems to me your interpretation is hardly legitimate.

You say, "I have concluded to answer the same lot of questions myself, and then the readers of the American Bee Journal, as well as the Doctor, can see how we agree in the matter." It hardly seems there can be any intelligent comparison of views when we are answering questions materially different, as the questions are made by our different interpretations.

In order that there may be any fair opportunity to see how we agree, suppose we answer categorically the same questions. I will send the editor a numbered list of the questions I understood to be involved in the case, together with a list of answers. He will send the questions to you, then when he gets your replies, he can print at the same time the questions and our replies. The questions I shall send will be just the ones I understood "Iowa" to mean, and just in the way I think he meant them. If you think it unfair for me to have the chance to formulate the questions, you will please formulate another set to suit yourself, and we will both reply to them. Then we can tell something about how we agree, for as the matter now stands it would be impossible to tell just how far we agree by reading the replies we have each made.

McHenry Co., Ill.

Various Remedies Suggested for Bee-Stings.

BY C. P. DADANT.

THERE is no end to the list of remedies offered for the sting of a bee. That none of these are infallible probably depends upon the fact that the wound made is very minute, the sting itself being very much finer than the point of the finest needle, which, when compared to it, looks thru the microscope like a coarse bar of blunt iron. So the remedies we apply have little if any chance of being put where they will do good, as it is only thru the pores of the skin that they can have any influence, while the poison, forced under the skin, has been distributed into the blood thru the minute veins and arteries.

Owing to its great fluidity its distribution into the system is about as prompt as that of a similar quantity of alcohol. For this reason the best remedies are perhaps ammonia, or spirits of camphor, but writers also recommend carbolic or phenic acid, lime-water, salt-water, cold water, yellow clay dissolved in saliva; and among vegetable remedies, honey, oil, vinegar, mint, raw onions cut in two and applied on the wound, bruised parsley, etc. Others advise rubbing, or sucking the wound. Suction will help if done at once, but after a few seconds the poison has dissolved and spread into the blood. Cold water alleviates the irritation, and is good when the stinging is very painful, but it does not cure it. Rubbing simply serves to spread the irritation to a greater surface, and prevent local swelling. It is not to be thought of in cases of severe stinging.

It is very probable that of all these remedies the most

practical is ammonia, if it can be used promptly on the skin, as it will penetrate readily, and, in cases of very severe stinging, it has been recommended internally in small doses mixt with water. It is quite likely that severe cases of stinging may be treated successfully by the methods used in cases of snake-bites. Authorities seem to agree on the bee-poison being a strong acid which can only be neutralized by alkalis acting directly upon it, and it cannot well be reacht when in the system, except by internal remedies.

The reason why so many remedies are recommended, each having its supporters, is made very plain by Reaumur. He says that one of his friends, named Du Fay, having been stung on the nose by a bee, tried olive-oil on the wound and found that the pain was stopt in a few instants. Reaumur then tried the same remedy on one of his servants who had also been stung, and the result was the same, the wound did not swell, and the pain disappeared promptly.

This seemed to prove the remedy good, so he again tried this method on the following day on another person who had been stung on the forehead, but altho the man at first imagined that this had cured him, a quarter of an hour had scarcely elapst before his forehead was swollen so that he could hardly open his eyes. Other trials evidenced to Reaumur that the more or less pain the greater or less swelling was due not to the remedy, but to the location of the wound, to the greater or less amount of poison injected into it, and above all to the physical condition of the person stung, some persons being very sensitive to stings, and suffering greatly from a small amount of venom, while some others are almost entirely immune, either from previous inoculation of the same kind of poison, or by their peculiar and natural physical condition. So one person will be able to withstand two dozen bee-stings about the body without apparent suffering, while another may become very sick from a single sting.

That inoculation of this poison is a help against further suffering is evidenced by hosts of apiarists. I have myself, every spring, the evidence that the system becomes used to the poison, for at the beginning of every season I suffer far more from the first stings received than from others later. It would seem that in all diseases Nature labors to furnish an antidote.

But to a novice it looks rather discouraging to have to become inoculated by stings in order to become proof against them. Many persons hesitate to work with the bees for fear of the stings. Yet in the majority of cases it takes but little firmness to overcome the first dread. The pain, like many other nervous pains, is most excruciating if you dread it, but becomes slight when the first fright is over.

Then with a little care and proper handling no one need be stung to any extent. We may be kickt by a horse, we may be bitten by a dog, yet the fear of kicks or of dog-bites will never prevent us from keeping and handling useful animals.

Hancock Co., Ill.

Apis Dorsata—Information About It.

(Extract from Dr. Watts' Dictionary of the Economic Products of India, republished in *Gleanings in Bee-Culture*.)

DESCRIPTION.—The bees of this group differ from *Apis mellifica* in being larger; in building $4\frac{1}{2}$ cells to the inch; in the shape of the abdomen; in having 13 rows of bristles forming the pollen-basket; in the relative positions of the eyes and ocelli, and in a very slightly different arrangement of nervures of the anterior wings. It would seem that this bee does not build larger cells for drones than for workers, and that the drone is similar in shape and size to the worker, differing principally in the head, which resembles the head of the drone of *Apis mellifica*. It builds one large comb, 3 to 5 feet long, two or more deep. The brood-comb is $1\frac{1}{4}$ inches thick, and the store-comb much thicker. Altho both *Apis dorsata* and *Apis florea* are normally single-comb bees, under exceptionally favorable circumstances they build a second comb, and their single combs are built much larger than otherwise usual; *e. g.*, *Apis dorsata* building in rock cavities; and a comb of *Apis florea* built in a dwelling-house was found to be about 5 feet in area, in addition to being in some places double, the comb of this bee being usually single, and perhaps less than one foot in area. Probably in all these very large nests there are several queens, and they are not comparable to single colonies of *Apis mellifica*. The arrangement of the stores and brood is the same as in other species. *Apis dorsata*, as found in India, is exceedingly constant in size and color. It is found in forests, but frequently builds in town. It is re-

puted to be very vicious; but unless disturbed it does not attack, and could be handled by some of the measures usually employed by bee-keepers.

HABITAT.—*Apis dorsata* is found all over India, but not at great heights above sea-level. It is said to be found at 2,000 feet or more in Bhutan, but may justly be termed a tropical insect indigenous to the plains.

ECONOMIC INFORMATION.—The large size of the comb and bee has excited hopes of this insect proving, under cultivation, of great economic value, and European bee-keepers have endeavored to obtain colonies of it. Mr. Benton, a dealer in foreign bees, went to Ceylon for the purpose; but he was unfortunate in his efforts, for the queens died. He states he does not consider them so vicious as reputed, when once hived, but he gave up the attempt to cultivate the species. Several years previously, the writer undertook to obtain colonies, if likely to prove useful in Europe, but did not hive any, as it was considered better first to investigate the economic value of other Indian species. The reasons against any attempt to cultivate *Apis dorsata* in hives are:

1. It builds naturally in the open.
2. It builds normally only one comb, so that the honey cannot be removed without removing the brood also.
3. Altho it builds a very large comb, this one comb is not so great in cubic capacity, normally, as the combs built by a colony of *Apis mellifica*, which is readily cultivated and well understood already.
4. It is found only in a tropical climate, and in this respect differs from *Apis mellifica* and *Apis Indica*, the most productive varieties of which are apparently indigenous to localities having more or less severe winters.

Apis dorsata probably might be cultivated in a semi-wild state in the forests, and the produce largely increased by this means. The present practice of indiscriminately robbing every colony found of all its comb, stores and brood, might be replaced by a more rational mode of procedure; for, altho not hived, many of the processes applied in the economic management of *Apis mellifica* might be applied to the semi-wild *Apis dorsata*. The bees might be fed to stimulate breeding or to prevent starvation. Excessive swarming might be interfered with. Certain colonies might be selected to breed from, as in the old style of bee-keeping. It might be found practicable to remove only portions of the comb, and the bees might be induced to build on or in artificial structures more accessible than the branches of trees.

Large quantities of both wax and honey are taken in the forests from *Apis dorsata*. This wax appears to be bought by dealers, and some is exported. The honey is sold and mostly consumed locally, but is commonly of very inferior quality, being contaminated with pollen, the juices of larvae, etc. It is also commonly thin, and liable to fermentation. The use of a simple extractor, care being taken to ripen when necessary, and to grade it instead of mixing good and bad together—these and other simple improvements would greatly increase the value of the honey.

It appears highly probable that most of the honey produced by bees building in open air is thin, and requires ripening by evaporation to remove its liability to fermentation. Out of 60 to 70 specimens sent to the Calcutta exhibition, very few were free from fermentation.

Should a Laying Queen be Given the Parent Colony?

BY G. M. DOOLITTLE.

A CORRESPONDENT wishes me to tell the readers of the American Bee Journal whether I think it advisable to give a laying queen to the parent colony immediately after it has cast a prime or first swarm, as is advised by some.

This is a very interesting subject, and one which has much to do with our honey crop, if we are situated in certain localities. The whole matter of profit, resting on whether we should give such a queen or not, must be decided by our location. If the locality gives a continuous yield of honey, then the giving of a laying queen immediately after the first swarm issues will prove a profitable investment; but if the location is one like the average location, which gives a good yield of honey at one or two stated periods during the season, then the giving of a laying queen at the time of swarming will generally prove decidedly unprofitable.

Among my earliest recollections in bee-culture was the story that the bee-keeper who wish to secure the best results from his bees should have on hand, and give to colonies, queens as above, and the reason advanced for so doing was that the time lost by the parent colony in rearing another queen to take the place of the one going with the swarm was equivalent to another swarm of bees. I have experimented largely along this line, and the truth of the statement—that the time lost by the bees in rearing a queen in natural swarming is equivalent to a swarm of bees—is the first reason that it will not prove successful in locations similar to my own, which gives, at most, only two honey-flows each year.

If it were bees I was after, the case would be different. With me, white clover yields only enough honey to keep the bees breeding nicely, and prepares them so that they swarm mainly from June 15 to July 1. Our honey harvest is from basswood, which blooms from July 5th to the 15th. Now all who are familiar with natural swarming know that the bees are comparatively few in numbers in spring, and increase by the rapidly-increasing brood produced by the queen, which, in due time, hatch into bees until a swarm is the result. By giving a laying queen to a colony immediately after it has cast a swarm, we bring about the same result (swarming) as before, for we place the bees in the same condition. The only difference is, that having plenty of brood they build up quicker, and are prepared to swarm in a shorter time. As this second prime swarming, brought about by giving the laying queen, comes right in our basswood honey harvest, it cuts off the surplus honey; for it is well known that bees having the swarming-fever do little or no work in the sections, and if allowed to swarm, the object we have sought after (section honey) is beyond our reach. If this laying queen had not been given, and we had worked so that no after-swarms had issued, we would have found that the young queen, which was to become the mother to the colony, would have emerged from the cell, as a rule, in eight days after the swarm issued, and in ten days more she would be laying, which would bring the time of her first eggs at about the time basswood would be yielding honey nicely.

During the period between the time when the swarm issued and the young queen commenced laying, the bees, not having any brood to nurse for the last half of the time, consume but little honey; hence, as fast as the young bees emerge from the cells they are filled with honey, for bees not having a laying queen seldom build comb, nor take willingly to drawing out foundation in the sections. Thus, when the young queen is ready to lay she finds every available cell stored with well-ripened honey. At this point the instinct of the bees teaches them that they must have brood or they will soon cease to exist as a colony. A general rush is now made for the section: the honey from below is now carried above, so as to give the queen room, and in a week to ten days we have, as a result, the sections nearly filled with honey, and fully completed a day or two later, if the season is not unusually unfavorable.

In this way good results are obtained in such a location as this, while, if a laying queen is given, the basswood honey season is nearly or quite used up by the colony becoming "sulky" with the swarming-fever, if they cannot have their own way.

After basswood we have a honey-dearth, hence the bees from the introduced queen are of no practical value, but, on the contrary, become useless consumers. On an average, it takes 21 days from the time the egg is laid to the perfect bee ready to emerge from the cell. Then if the colony is in a normal condition, this bee does not commence labor in the field till 16 days old; hence the egg for the honey-gathering bee must be deposited in the cell 37 days before the honey harvest begins, or else they are of no value as gatherers from the fields, altho they may do some inside work in the hive near the end of the basswood harvest. As basswood is all gone before the eggs of the introduced queen become honey-producing bees, and as the larger part of them die of old age before buckwheat or fall flowers yield honey, a great gain is made all around by letting each old colony having cast a swarm rear its own queen, for thereby we do away with the desire to swarm in the midst of the basswood honey-flow, and the expensive feeding of the larvae, which are in turn to become expensive consumers of the honey of the hive.

These things are well worth looking into by every person keeping bees, for if brood-rearing is used advisedly, with an eye on our location, we shall find that great profit will result therefrom.

Onondaga Co., N. Y.

THE AFTERTHOUGHT

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

HAND-SHAKING CONTAGION ALL AROUND.

What an assortment of diseases presidential candidates must have at the close of a campaign, if Dr. Peiro's anti-hand-shaking raid on page 331 is well founded! And, alas, perhaps we dissentants are only but dogs, chained to the hind axle of the car of progress. In spite of our hanging back and yelping, on it goes, and we with it. Give us facts and statistics, Doctor; and when we've had *enough* of them we'll give hand-shaking up, and wave at each other. It may be different with soft-handed, in-door folks, but we (some of us) incline to incredulity about a hard-handed, laboring-man catching anything by a shake. Drum up some itemized facts, and fire them into us.

But, let's see, Doctor; if we learn the A of your reform, won't we have to learn B also? There's the habit of knocking on doors now. The human knuckles are very liable to abrasions—and alas for the millions of poor bee-keepers who have died of leprosy or thunderstroke, caught by knocking on doors, where some leprous or thunderstruck chap had knockt just before!

FRAME FOR EXTRACTING.

C. A. Bunch, page 321, is just longing to "climb up some other way" with his deeper frame for extracting, when up thru the narrow way of perforated zinc is the true gospel. With any kind of frame above or below, the queen goes up too much.

SCREENS FOR MOVING BEES.

Davenport's moving screens, made to telescope on with eight bits of lath, and then be tied with two big strings, are doubtless practical; but, then, wire-nails are also practical, and so much simpler. Page 322.

BUSINESS ON A BUSINESS SCALE.

This is business on a business scale, I thought as I read a long way into Herbert Clute's article, on page 322; but where is there anything to comment on? Toward the latter end I began to find plenty of comment-ables. Nice and unique to have each colony store five or six pounds of stump honey from the winter's choppings. My skepticism found food in that aster honey alleged to be better than basswood. Still, may be he's right. Here asters are abundant late in the season, and seldom or never seem to yield any surplus—perhaps because they do not bloom until surplus-promoting weather has all gone by. It is a composite flower, however, with the general flavor of its order, and why should it yield other than fall-flower honey?

The bee-yard, graded into the side of the hill was one of the best things—cellar just pusht still further in. What with the grading, and what with the trees all round, no tight board fence could begin to equal it. A moderate amount of hoeing ought to keep weeds from getting any hold there, and secure that high desideratum—a perfectly clean yard.

But, on the whole, that groceryman is my choice. Actually makes honey the centerpiece of his show-window—big barrel of candied basswood honey with the staves all taken off, sliceable with cheese-knife, and provocative of endless questions—and sales. No wonder it all went in a week. First have a really good thing; then give the public mind a right good stirring up. See?

THE GENDER OF BEE-PRONOUNS.

And "Afterthought" must be afterthoughted itself, this time. Page 324. I used to get mad when the editor (of the ancient "Exchange") changed the gender of my bee-pronouns (thought I understood our splendid and delicate and expressive English language as well as he did, don't you know?) but I never said anything—just kept right on, same as before, and by and by he got tired of reconstructing me. This time I didn't even get mad—laught a merry laugh to see that they had mist one at last, out of a string of wrong-

speckled pronouns. It was "his" and not "its" voyage that went to wreck.

And at this point let me stop laughing, and soberly take a teacher's chair and tone. Interest and sympathy are great elements to conjure with when we write. No one can have very much sympathy when a little organism has *its* voyage wreckt. But when reading how a little *fellow* had *his* voyage wreckt there is, almost necessarily, a touch of pathos. The ideas, "little fellow" and "its," refuse to fit together, don't you see?

PAINTED QUEENS.

Who knows whether painted queens (page 330) would stay painted? or whether, like black walnut stain on a boy's hands, Nature has some trick whereby paint would gradually disappear? Tater is quite sure that those who actually paint actual queens will know more about that manipulation than those who stop at reading and reflection.

HONEY-DEW FROM THE SKY.

On page 332, we score one more man who has seen honey-dew fall from the sky—W. T. Alexander. *Enough* such witnesses will convince us—just as enough grasshoppers will stop a train of cars. It's a little hard on the grasshoppers, tho—and perchance a little trying on those who throw themselves before the wheels of our incredulity, as Mr. A. does here.

"PETER PIPER PICKT A PECK OF PICKLED PEPPERS."

And behold No. 22 confronts us with the faces of 17 Canadians—no relation whatever to the forty—. Happens to be the first time I have seen the "Picker"—D. W. Heise. 'Pears like the Kanuckshire pickings are not very tall, if so short a picker can pick 'em so nicely.

VALUE OF BEES IN POLLINATION.

On page 338, Prof. Cook, as usual, speaks with a master's authority. I cull two ideas for repetition: 1. Other insects did once do something at the pollinating service; but *when we mass fruits in great orchards* the hive-bee is the only practical resource. 2. The fact that Nature is disinclined to, and often refuses altogether, *near* fertilizations (same flower, or same exact variety) is a sure and undeniable thing. This thing is the underlying fact which calls peremptorily for the presence of bees. Let us be diligent in the work of convincing our fellows of this, and in keeping it in their minds.

PUTTING ON SUPERS.

Another disagreement. On page 339, C. P. Dadant says for us not to put on comb-honey supers as soon as we do extracting-supers (in certain cases); and Mrs. Axtell, on the very same page, says putting on sections early is the best thing she ever tried to keep down swarm fever. I think I'll be ladies'-man this time.

ALSIKE BOTH LONG AND SHORT LIVED.

Thirty-one successive winters and no winter-killing is quite a record for Alsike (latitude 42 on the Mississippi)—quite a feather in its cap, which ought to count something in our favor eventually. F. A. Snell, page 340. But (bane and antidote) E. S. Miles, page 340, says all his Alsike is winter-killed, and some white clover is left.

COTTONWEED INFORMATION WANTED.

I think Mr. Allen, page 340, should have told us more about the West Virginia cottonweed that yields more than the basswood. We want to get acquainted with it.

PROLIFIC FOUL BROOD BACILLUS.

Two generations in an hour, says Thos. Wm. Cowan, of the foul brood bacillus. That beats the children of Israel in Egypt, decidedly. Twice *one* does not impress us much; but twice the billions and trillions seems like business for a half hour of history. Page 341.

DOUBLE-WALLED HIVE WITH NO SPACE BETWEEN.

H. S. Jones, page 341, is unique in using a double-walled hive with *no space between walls*—tells us *why* he does so pretty well; but still it looks a little like fencing a pasture with no space for grass between the fences. Wonder if he prefers his meals with no between-times.

PUTTING UP FRUIT WITH HONEY.

And so J. H. Hermance's four bushels of plums preserved in honey (two pounds honey to one pound plums) were manifestly too poor to offer to the public till three or four months' time ameliorated them—and then they sold

fairly well. Page 349. To sift out the actual facts from the bee-feverish enthusiasm with which they have got mixed, is quite desirable in this matter of putting up fruit with honey.

DR. MILLER'S FOUNDATION-SPLINTS.

Thanks to Dr. Miller for the full information about foundation-splints, on page 342. Wood separators piled and sliced again—and well cooked in wax—and prest in place just hot enough. We see.

THAT PINK COMB IN MARYLAND.

That pink comb Maryland tells of is so rare in the United States as to provoke doubt about it; but as the commercial beeswax of the island of Jamaica is a deep pink, pink comb must be plenty down there, one would say. Or does a very red propolis bestow the pink?

KEEPING ENTRANCES CLEAR OF SNOW.

For deep snows (if you think snow in front any damage) Mrs. Griffith's way, page 350, is tip-top. Wide board set up in front, touching at top, and *not quite* touching at bottom.

SOME RECOVERED FROM THE BEE-FEVER.

End of the bee-fever! Not one of the 28 heavy fellows who answer the questions has tried the Golden method. But possibly the "boys" have not so universally recovered yet.

COGITATOR.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Perhaps a Queenless Colony.

We had two colonies of bees, but one died last winter, and at the other we found a great many dead bees under the hive. This summer, what are left, do not work at all. We think the queen is dead. Do you keep queen-bees for sale? NEW YORK.

ANSWER.—No, I don't keep queens to sell, but you can get them from those who advertise in this journal. It is just a little doubtful, from what you say, whether it would be advisable to give a queen to your bees. If they have had no queen this spring at all, there will be none but very old bees present, and it will be hard to get them to accept a queen. Moreover, these old bees will now be dying off very rapidly, and at their age will not make good nurse-bees, so even if you should introduce a queen successfully the colony would hardly be worth much. Your better way would be to let these go and start with a new colony. Of course, if it should turn out that they are not queenless, that's another thing.

Preventing Swarming and Caging the Queen.

Our main flow here comes from clover, in May and the former part of June. My plan is to control swarming thru May and work for increase in June, and by so doing take advantage of the flow.

1. Do you approve the plan?

2. In caging the queen above the brood to prevent swarming, is it necessary to put a retinue of workers in the cage with her, or will the bees feed her from the outside, using the Miller cage?

WILLIAM.

ANSWERS. 1. Yes, if you can keep your forces together till toward the close of the harvest it will be better for the honey crop. But look out that you don't adopt some plan that will hinder the bees more than to let them swarm. If you have some plan in mind that you have not yet thoroughly tried, better try it on a small scale and not with your whole apiary. If you allow only one swarm to each colony, getting all the working force into the swarm by setting the old

colony beside the swarm for a week and then moving it to a new place, your force will be kept together pretty well for storing, and it will be time for you to adopt in general some other plan after you have tried it on a small scale and know it will work well for you.

2. No need to put any workers in the cage with the queen. They may die there, and dead bees are poor company. The bees will feed the queen all right thru the wire-cloth of the cage. You speak of caging the queen "to prevent swarming." Now, I'm just a little afraid you're going to get into mischief. Simply caging the queen will not prevent swarming—indeed, if you cage the queen and leave her caged long enough, you'll be pretty sure to make a colony swarm that would have had no thought of swarming if you had not caged the queen. For the bees will rear young queens, and the first one out will be likely to issue with a swarm. But you say you mean to cut out queen-cells. Well, some report good success with that sort of management, and some have not succeeded with it. Don't you go into it wholesale till you know how it will work with one or two colonies. The chances are that you'll not like the plan. I tried it on a pretty large scale, and was not one of the successful ones.

Queen-Bees Wanted—Feeding Bees in June.

1. If you have queen-bees for sale, please quote prices. I mean pure Italian queens.

2. In this locality bees are gathering very little honey; would it be advisable to feed at this time of the year?

ILLINOIS.

ANSWERS.—1. I have no queens for sale.

2. If the bees are not gathering enough for their daily needs, and if the combs are empty of stores, it may be absolutely necessary to feed. Sometimes it happens, even in June, with plenty of white clover bloom, that bees don't get enough for their daily living. At such times the queen will stop laying, and no honey being in the hive the bees will suck the juices out of the unsealed brood and throw the skins out of the hive. If no stores are in the hive it isn't a bad plan to feed anyhow, for the feed will not be wasted, and it isn't best to wait for actual starvation.

The Barber Plan of Forcing Bees into Sections.—Mrs. A. J. Barber says in *Gleanings in Bee-Culture* that one reason she puts on a shallow extracting-super before putting on sections is because the queen will lay in these extracting-supers, and then the bees will fill the sections between the two lots of brood, but will not go up thru the sections to lay again in the extracting-combs. The extracting-super being above does not in the least affect the whiteness of the sections.

The Big-Little-Hive Question seems to be one that will not down. Chas. Dadant, replying to G. M. Doolittle in *Gleanings in Bee-Culture*, urges the difference in swarming as making the large hive superior, saying that in his large hives the home apiary of 80 colonies did not give 10 swarms in three years, while Mr. Doolittle last year alone had 548 swarms from 49 colonies. As a parting shot he quotes Mr. Doolittle as reporting that in 1877 he had a colony in a specially constructed hive with 32 frames which had about 99,500 bees.

One Hive-Story or Two.—For some time Editor Root, of *Gleanings in Bee-Culture*, has been advocating large colonies, such as could not be contained in an 8-frame hive, but has maintained that if additional room was given by a second story it was just as well as to have more room in a single story. Mr. Dadant does not agree. Challenged by A. N. Draper, Mr. Root has had built a number of hives just like the 10-frame Langstroth in all respects except that the frames are two inches deeper. These are to be given a fair trial in order to help settle the question. Dr. Miller does not want to believe that large frames and hives are better, because the smaller hives are so much nicer to haul

and to handle, but he has fears that the two-story hives with smaller frames are not so good. Mr. Poppleton thinks there is no question that the greater capacity all in one story is much better for extracted honey, altho he doesn't pretend to understand why. Mr. Root says orders are on the increase for 10 and 12 frame Langstroth hives from extracted-honey men of the South, and the 8-frame size is preferred by comb-honey men of the North. Quite a few are ordering what he calls Draper's "barns" to test alongside of the regular 8-frame hives.

Comb versus Extracted Honey.—In a discussion reported in the Canadian Bee Journal, Mr. Holtermann took the ground that the beginner should be discouraged from producing comb honey. He estimated that 70 pounds of comb could be produced to 100 of extracted. Mr. Gemmill thought this might be right some years, and some years wrong. Mr. Davidson thought the amount of comb was placed too high, and Mr. Darling said that not far from him first-class comb honey was sold for 5 cents. No one seemed ready to champion the cause of comb honey.

Queens Reared in Queenless Colonies.—Dr. Miller seems to have in W. W. Somerford an ally to help support his heretical notion that good queens can be reared in a colony from which the queen has been removed. Mr. S. says that such queens have given him entire satisfaction for years, seeming to be just as good as queens reared by the Doolittle plan, except at times just after a honey-flow. At such times he is obliged to do considerable culling in order to get large queens that will mate quickly, and early mating and early laying he considers the best evidence of a good queen.—Gleanings in Bee-Culture.

Inspecting Queens in the Cells.—W. W. Somerford relates in Gleanings in Bee-Culture that when rearing queens in foul-broody apiaries he found it essential to examine the contents of the queen-cells before the time of hatching, otherwise there might be in a cell nothing but a dead larva. He made a cut across the base of the cell with the little blade of a sharp cell-knife, tipped the blade sufficiently to open the cut so he could have a good look at the occupant, then mashed the cut nicely together, and with one or two delicate touches of the hot fire-box of a smoker it was welded together to the satisfaction of the bees.

Travel-Stain.—Editor Doolittle, in the Progressive Bee-Keeper, refers to the discussion that has been going on as to the cause of travel-stain, and after referring to the theory that dark bits of wax from the brood-combs are incorporated in the cappings while they are in the process of construction, says:

"While I agree to this part, I also believe there is such a thing as 'travel-stain,' or something of the kind, for I have yet to see a single section of honey which has been left on the hive three weeks after it was finished that was as spotless snow white as it was on completion; and if left on two months it is discolored to a sufficient extent to throw it into a lower grade when putting up for market. I quite agree in this conclusion, for I have had combs built scores of times between old combs in the brood-chamber when fully one-half of the wax they contained was that taken from the old combs each side of the one being built."

Mr. Doolittle will have no great difficulty in having any comb-honey producer of experience and observation agree with him.

Stimulative Feeding.—Editor Gerstung, of the Deutsche Bienenzucht, sent out a series of questions regarding stimulative feeding. Of 15 replying, 8 thought the harvest might be increased by such feeding, and the other 7 would none of it. The reason for these opposite views is that stimulative feeding is a two-edged sword, a speculation upon the future, sometimes turning out well, and sometimes causing loss. All agreed that as to localities and colonies, the place for such feeding is where early harvests are best, and the colonies to be treated are the strong ones. Eight would feed pure honey, others would add some albuminous substance, as pollen, flour, milk; 2 would feed sugar if honey was yet in the hive, and one would feed sugar unconditionally. Feeding should begin about 6 weeks before the full harvest, and cease about 6 weeks before its close. Food in small portions often repeated, preferably at nightfall, with great care to prevent robbing. The conclusion was that stimulative feeding was advisable only in the hands of the careful and experienced, being almost sure to bring bitter disappointment to the novice.

BIOGRAPHICAL

MR. J. W. OGLESBY.

The subject of our sketch this time is Mr. J. W. Oglesby, a bee-keeper living in Logan Co., Ark., whose picture appears herewith, and who gives the following short account of himself:

I was born May 29, 1858, near Knobnoster, Mo., and brought up all over the country. In 1863 my parents moved to Douglas Co., Kan., thence to Nebraska, thence to Hill Co., Mo., thence to St. Clair Co., Mo., all within a period of four years. There we lived until I became of age, and I was married to Miss Virginia Peeden, who died in 1888, leaving me with two children.

In 1889 I was married again, this time to Miss Nannie Poorman, of Milesburgh, Pa., who is still alive and the mother of four prattlers—three girls and one boy.

I have followed nearly all vocations, from the cow-puncher to the merchant (my present vocation), having been farmer, school teacher, book agent, sewing machine agent, insurance agent, "patent right man," and about all the rest of the ways of making a living, but finally I settled down with a small stock of drugs, and for the last few years I have been making some money in drugs coupled with bee-keeping. This latter industry is my chief delight.

In March, 1895, I bought a colony of golden Italian bees, the "A B C of Bee-Culture," and subscribed for the American Bee Journal, and "at it I went." With hard study I managed to conduct my amateur apiary in such a manner

that I got about 40 pounds of fine honey the first year and one swarm. The following winter I bought and Italianized some blacks, and have since run up, by artificial swarming, to about 30 colonies—last summer—but I doubled up to 23 colonies in the fall. I sold 4 colonies and lost 4 by robbing this spring; however, the 4 that were robbed were queenless, and there has been no honey-flow whatever here this spring, and I was afraid to go thru to examine for fear of inducing robbing, when the bees concluded to "go thru" themselves, which they did. Well, I can't say that I lost 4, either, as I doubled them over strong colonies that I was sure had queens, and I think I lost only a few bees, so I don't count that much loss, yet my count is 4 colonies less.

My bees are all in fine condition. I have the Adels, and better workers I never saw. I pride myself in keeping my stock pure and my colonies strong. I use the dovetail hive with Hoffman frames, and run up for extracted honey, for which I have a ready market here at home for all I produce, at 7½ to 10 cents a pound. I believe in large hives, even having some of mine 3½ stories high. I get more honey, and can control swarming better. Our products for this year were very good.

I hope the old American Bee Journal's shadow may never grow less.

J. W. OGLESBY.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

JULY 6, 1899.

NO. 27.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Writing for Publication.—In answer to a correspondent the Editor of *Gleanings in Bee-Culture* offers this paragraph:

"We use only about one-fourth of the manuscript that is sent in for publication. Perhaps some that we do use is not as good as some we refuse. If so, we err in judgment in our selection. It is seldom that any publication is interesting to every reader, from cover to cover. What will interest one will not another."

A very few of our contributors get terribly "riled up" when we fail to publish their pen productions. We print a good deal more than a fourth of the manuscript we receive. Of course, it is an editor's duty to select the contents of his paper, and he often errs in judgment, as Editor Root says, for he is quite human, just like the rest of imperfect humanity.

But, take it all in all, the correspondents of our bee-papers are a pretty nice lot of people. So are those who don't write, but prefer to keep their information to themselves. But it seems that more than ever before the bulk of the contents of the bee-papers of to-day is contributed by only a few writers, and those the old and thoroly experienced. It is far different in this regard from what it was 10 to 15 years ago.

Fashions in Bee-Keeping seem to be almost as evident and changing as in patterns and styles of ladies' dresses

and hats. Editor Hutchinson, of the *Bee-Keepers' Review*, seems to have had his attention called to this subject, doubtless on account of having several charming young ladies in his family (in fact, his children are all of the feminine persuasion). Here is his comment:

Fashions seem to change in bee-keeping in something the way they do in clothing. Last year the girls' shirt-waists were plaid. It makes no difference now whether the plaid waists are worn out or not, they must be laid aside for striped ones. Years ago the plain Langstroth frames were good enough. Then they must have metal corners. The corners proved a nuisance, and were laid aside. Next came the Hoffman style of frame. Now some of the folks are talking of making frames and hives two inches deeper. Then there are the changes in supers, separators, sections, smokers, etc. So it goes on until sometimes it seems as tho changes were made in these things simply to have something new to sell, and so that we bee-journal fellows can have something to talk about. Perhaps I am too severe—but then, I am taking my share of it.

In all seriousness, I suppose new things must be tried; but don't throw away the old for the new just because the new is *new*.

But Editor Hutchinson ought not to be too hard on the folks that are getting up new things. He mustn't forget that *he* started a *new* bee-paper some years ago, and very few bee-keepers, comparatively, have ever had the daring to do that, and expect all other bee-keepers to change from the old and long established papers to the new one.

Of course, all new things in the line of bee-fixtures do not prove of particular value, but from out the many suggestions and inventions there oftentimes comes something that is truly wonderful as well as eminently useful. We say, try some of the new, but don't throw away the old until satisfied that the new is really an improvement, and is well worth replacing the old.

England's Honey Supply.—Mr. Benj. G. Irving, of New York, some time ago sent us the following interesting clipping, which originally appeared in the *Westminster Gazette*:

English bees are unable to produce as much honey as England needs. Every year we have to import 2,250,000 pounds, of which the declared value is 31,000 pounds sterling, or about 3½d. per pound. Among the countries engaged in supplying our markets with this product, the principal are the United States, Chili and Peru, the other contributors including the British West Indies, France, Australasia, Canada, Germany, Italy, and the Spanish West Indies. No statistics of the quantity of honey produced in the United Kingdom are obtainable, but it is quite evident that bee-keeping is capable of being much more profitably developed than it is.

A Hint for Our Advertisers.—It isn't often that we get anything that we can publish especially for our advertisers, but here is a letter that we think some of them may profit by:

DUBUQUE COUNTY, IOWA, June 26, 1899.

EDITOR YORK:—I am a beginner in bee-keeping. I take the *American Bee Journal*, and enjoy reading it very much, so you can count me a steady subscriber.

I read all the advertisements, and I see there are a great many who sell bee-keepers' supplies, and can fill orders on very short notice; and I believe they can, because I sent a \$12 order for bee-supplies to Ohio; I received the goods six weeks afterward.

Then I sent an order to Des Moines, Iowa, June 6, for \$2.00 worth of supplies; they haven't come yet, but I guess they will pretty soon.

Last winter I sent a postal card to one of the large manufacturers of bee-supplies (who advertise in the *Bee Journal*) for a catalog and price-list; they wrote me they were just out of catalogs and price-lists, but they were going to have some printed, and would send me one. It has not come yet, but I guess it will.

I wrote to another big firm for their catalog; they have not sent any; guess they are out, too.

How long do you think it would take to get bee-supplies from Chicago to Dubuque, Iowa? I may need a great many next year. I know how long it takes to get anything else, as I have a great deal of stuff to come and go by freight and express.
SUBSCRIBER.

We think that we need only answer the question in the last paragraph above. If the bee-supply dealer in Chicago has the desired goods in stock, it ought not to take much longer for an order for bee-supplies to be filled from Chicago than for any other kind of goods. But sometimes it happens that dealers or branch offices run out of stock, and have then to wait until a new supply comes from the factory. This may cause delay in some cases.

But, ordinarily, we think our advertisers mean to be prompt in caring for their business. Still, this season we have had the most complaint against certain queen-breeders. It seems that at least one of them not only did not send queens, but was terribly slow in returning money. Now, it seems to us that if queens cannot be sent promptly when ordered, the customer should be notified, and if he cannot wait, then return his money so he can order elsewhere. It is very annoying, and may cause loss of colonies, when queens are not received when expected. Queen-breeders cannot be too careful to be prompt at all times. A prompt, straight-dealing advertiser may not be a "thing of beauty," but he may be "a joy forever"—or at least so long as he advertises and does business.

Some Honey in 1899—Diseased Brood.—Prof. A. J. Cook, of Los Angeles Co., Calif., writing us June 20, had this to say in regard to these two subjects:

I find as I go out for flowers nearly every day the bees are very actively at work on the white sage—*Ramona polystachia*. The bee-keepers along the hills are all sending very fine comb honey to our grocery stores, which readily sells at 12½ cents a pound, and this, too, altho the sections are far from being well filled. I should have said per section instead of per pound, as all sections sell for 12½ cents, no matter how light; this is what the groceryman pays, and not what he sells for. We see, then, that what I suggested at the beginning of the season has proved true. Tho we have less rain than last year, it came at such favorable times that we shall yet get something of a honey crop.

I still am receiving many samples of diseased brood from bee-keepers, not only in California, but from those in Arizona. With the specimen often comes the information that there is plenty of honey in the hives, and that there could not possibly be any starvation among the bees. This is certainly a very important matter. This disease is entirely different from foul brood. It certainly seems as if the bees die from some cause not understood, and then decay by natural processes sets in. The important question to determine is what makes the brood die. In all cases which I have examined about here, there seems to be none of this trouble, altho in 1894 I saw not a little of it among the bees here. If the malady is the same that was so prevalent then, we may certainly hope and believe that it will not be of long duration. I quite believe that it was a benefit to me in that year, as it thinned out the bees when numbers were of no account, and so it was necessary to feed less. I had to feed my bees to save them, and as soon as I commenced to feed the disease disappeared. A. J. COOK.

Bees Averse to Dark Color.—We have just learned that there is a large bee-keeper in Quincy, Ill., who is also an extensive poultryman. He has given up the raising of black and dark-colored chickens because the bees sting them so. He will raise the white and lighter-colored varieties hereafter. Who was it that said all colors look alike to bees, and that they would not sting dark objects any more than light ones?

The Premiums offered on page 426 are well worth working for. Look at them.

MR. J. M. HAMBAUGH, of San Diego Co., Calif., wrote us June 20:

"We will have one-fourth crop of honey in some localities in this county; in other localities bees are starving."

MR. HENRY ALLEY, of Essex Co., Mass., wrote us June 24:

"We have had plenty of rain lately, but the white clover was ruined before the rain came. Bees are idle."

MR. J. T. HAIRSTON, of Cherokee Nation, Ind. Ter., writing us June 22, said:

"My bees are doing nicely. I have 122 colonies from two four years ago. I prize the 'Old Reliable' highly."

MR. S. A. NIVER, of Tompkins Co., N. Y., made a two-days' visit recently to The A. I. Root Co. Mr. Niver is a brother-in-law of the late Miles Morton, of the same State. He (Mr. N.) has a well-earned reputation for being one of the best honey salesmen known. We have met him, and—"he's—all—right."

MATE WILLIAMS, of Wadena Co., Minn., writing us June 20, reported:

"It has rained nearly every day or night so far this month. The raspberries are in bloom again. Last year I sent raspberry extracted honey to Omaha, and it was awarded a silver medal and a diploma, of which I am very proud."

MR. J. H. MARTIN (Rambler) has this paragraph in *Gleanings in Bee-Culture* for June 15, about orange-blossom and sage honey:

"Several tons of honey have been harvested near Riverside, where the bees had access to the orange-orchards. The orange-blossoms yielded a good amount of nectar this year. A limited amount of sage honey is coming into the Los Angeles market, showing that there are a few favored locations. There will be hardly enough, I think, for home consumption."

DR. A. B. MASON, of Toledo, Ohio, Secretary of the United States Bee-Keepers' Association, wrote us June 26:

"For the last two days the bees have been getting a little surplus—the first this season. Basswood and white clover yield none, but sweet clover is giving the bees a little to do—not much."

Next week we will be able to make some announcement as to the railroad rates, etc., for the Philadelphia convention in September. Look out for them.

MR. D. W. HEISE is outrageously slandered in the June Canadian Bee Journal. A correspondent, referring to his humor, quietly asks: "Is Heise not a German?" In reply, Editor Holtermann makes this public accusation:

"Yes, Heise is certainly a German. I do not know if he ever waylaid an Irishman and stole his wit, or how he acquired it, but we may rest assured he never came by it honestly."

Now, being somewhat German ourselves, we feel like helping Mr. Heise. The idea of a German having to steal wit of an Irishman in order to possess any! We wonder where Editor Holtermann has been all his life! We hope the next time they meet, Mr. Heise will show Mr. Holtermann the difference between German and Irish wit. If the meeting-place shall be in Philadelphia, about Sept. 5, 6 and 7, we will try to be on hand to help Mr. Heise, in case he needs any assistance when he attempts to put a Dutch "Holter" on that "Irish" "man" of the Canadian Bee Journal!

Why Not Just Double

The List of Subscribers to the Old American Bee Journal?

We really believe that if ALL the present readers of the American Bee Journal were so inclined, they could help to double its regular list of subscribers before August 1, 1899—or during the next 5 or 6 weeks. We do not find any fault with what our subscribers have done in the past toward increasing the list of Bee Journal readers—for they have done nobly—but why couldn't the doubling of the list be accomplished within the next month? We surely think it could be done, and in order that it may be easier for those who help in it, we will make a **SPECIAL NEW SUBSCRIPTION OFFER**, and also pay all who will aid in securing new subscribers. Here is the offer:

Six Months for 40 Cents to a New Subscriber....

Yes, we will send the American Bee Journal **EVERY WEEK** from July 1, 1899, to Jan. 1, 1900—26 numbers for only 40 cents, to a **NEW** subscriber. In addition to this we will send to the present regular subscribers, for the work of getting new 6-months' readers, their choice of the premiums mentioned below, but no premium will also be given to any new subscriber on these offers, under any circumstance:

For Sending 1 **New 40-cent Subscriber**
 — Your choice of one of the following list:

Poultry for Market.
 Our Poultry Doctor.
 Capons and Caponizing.
 Foul Brood—Kohnke and Cheshire.
 10 copies York's Honey Almanac.

For Sending 2 **New 40-cent Subscribers**
 — Your choice of one of the following list:

Dr. Howard on Foul Brood.
 Monette Queen-Clipping Device.
 Bienen-Kultur (German) by T. G. Newman.
 Dr. Tinker's Bee-Keeping for Profit.
 Pierce's Winter Problem in Bee-Keeping.
 Bees and Honey (160 pages, paper) by Newman.
 20 copies York's Honey Almanac.

For Sending 3 **New 40-cent Subscribers**
 — Your choice of one of the following list:

Bees and Honey (160 pages, cloth) by Newman.
 Bee-Keeping for Beginners, by Dr. J. P. H. Brown.
 Bienenzucht und Honiggewinnung (German) by J. F. Eggers.
 Advanced Bee-Culture, by W. Z. Hutchinson.
 30 copies York's Honey Almanac.

For Sending 5 **New 40-cent Subscribers**
 — Doolittle's Scientific Queen-Rearing.

For Sending 6 **New 40-cent Subscribers**
 — Prof. Cook's Bee-Keeper's Guide.

NOW FOR A GRAND PUSH FOR NEW SUBSCRIBERS!

It seems to us that with the above low rate to new subscribers, and also the premiums offered, we should get such a landslide of new subscriptions as will make us sweat to care for them during the next few weeks without any help from the hot weather. **WE** are ready now to enter the new names and mail the premiums. Are **YOU** ready to go out and get them, and then send them in?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

The Midland Farmer

(SEMI-MONTHLY)

The representative modern Farm Paper of the Central and Southern Mississippi Valley. Page departments to every branch of Farming and Stock-Raising. Plain and Practical—Seasonable and Sensible. Send 25 cents, silver or two-cent stamps, and a list of your neighbors for free samples, and we will enter your name for 1 year. If you have not received your money's worth at end of year, we will, upon request, continue the paper to you free of cost another year.

Headquarters FOR THE ALBINO BEE!

THE BEST IN THE WORLD.

If you are looking for the bees that gather the most honey, and are the gentlest of all bees to handle, buy the **ALBINO**. I can furnish the Italians, but orders stand, as heretofore, 50 to 1 in favor of the **ALBINO**. I manufacture and furnish **SUPPLIES**.

S. VALENTINE, Hagerstown, Md.

In the multitude of counsellors there is safety.—Prov. 11-14.

Starters and Drone-Comb in Sections

Query 05. If starters are used in sections large enough to about half fill them, will the bees be likely to fill out the remainder of the section with drone-comb? My only reason for using starters this large is on account of so much drone-comb. **CLINTON.**

P. H. Elwood—Yes.

J. M. Hambaugh—Yes.

E. Whitecomb—Not so likely.

G. M. Doolittle—Yes, they do for me.

Mrs. A. J. Barber—If the colony is in proper condition it will make no difference.

A RARE CHANCE

to purchase an apiary of 200 colonies of Italian and Carniolan Bees in 10-frame Langstroth and Dovetailed hives. The hives are two-story with 10 brood and extracting-frames in top story, all wired for extracting. Combs are straight and in fine condition; last year's crop of honey was over 500 gallons from 150 colonies.

Purchaser can occupy the present good and convenient location of two acres, well shaded, with a comfortable residence for a family, for \$1000 per month, within 100 yards of fast line of electric cars that go thru main part of New Orleans every 5 minutes. Mail service twice a day. Poultry-houses and yards at cost of wire-netting in fences, and some fine poultry for sale; also furniture in house.

All must be sold, and location abandoned on account of poor health. All honey, poultry and eggs can be sold in city home market at good prices. Correspondence solicited.

Queens

Untested Italian, 50c each; Tested, \$1.00 each. Queens large, yellow, and prolific.

E. W. HAAG, Canton, Ohio.

SAUC 11 Successor to THEODORE BENDER.

Root's Column

HONEY=PACKAGES.

If you have a crop of honey you will want packages in which to put it on the market. For comb honey you will be interested in our

No-drip Shipping=Cases

which we are prepared to furnish in various styles and sizes as listed in our catalog. They are packed in lots of 50 in carrying-crates suitable for shipping your honey in after it is put in cases.

For extracted honey you will want, for storing and shipping to market,

FIVE-GALLON Square Cans

two in a case. We provided ourselves with two carloads of these before the advance in tin-plate, so that, while they last, we can still sell at the old price, 10 boxes, \$6.00.

For putting up honey for retail we have a variety of packages in tin and glass, listed in our catalog. Of most of these we are also provided with a large stock.

Ball's Best Mason Jars, with Aluminum Caps.

We have a carload of these which we offer for July shipment at the following special prices, put up one dozen in a box:

| | PER DOZ. | SIX DOZ. | GROSS |
|-------------------------|----------|----------|--------|
| Pint Mason Jars..... | 45c | \$2.50 | \$4.75 |
| Quart Mason Jars..... | 48c | 2.75 | 5.00 |
| 2-quart Mason Jars..... | 60c | 3.40 | 6.50 |

No. 25 Glass Jars.

This is a very popular Jar for one pound of honey. It has porcelain top with rubber ring and tin screw band. We have them put up one gross in a barrel at \$5.50; or two dozen in a partitioned case, ready for re-shipping when filled with honey, at \$1.15 per box, or \$6.50 for six boxes.

Tin-top Tumblers.

We have two sizes of these, 1/2 pint, or 10 oz., No. 788, packt 21 doz. (252) in a barrel, at \$5.00 per barrel; or 1/4 quart, 16 oz., No. 789, packt 16 2/3 doz. (200) in a barrel, at \$5.00 per barrel. 200 of each size nested in a barrel for \$8.70.

THE A. I. ROOT CO.,
MEDINA, OHIO.

We use one-inch starters, and have no trouble with drone-comb.

□ S. T. Pettit—With exceptional cases, yes.
J. A. Green—Yes, they will very often do so.

Dr. C. C. Miller—Yes, to a considerable extent.

E. S. Lovessy—My experience is, as a rule they do not.

D. W. Heise—I will let the comb-honey producers answer this.

J. A. Stone—I don't know, as I have never tried it.

Mrs. J. M. Null—Yes. It is more profitable to use full-size starters.

E. France—it would be a mere guess with me, as I do not produce comb honey.

O. O. Poppleton—I have too little experience in producing section honey to answer.

A. F. Brown—A great many times they will. I would use full sheets or only a small starter.

Emerson T. Abbott—They may and they may not. That will depend upon circumstances.

R. C. Aikin—Yes, likely, particularly if none below, colony very strong, old queen or queen-cells.

Mrs. L. Harrison—What are your objections to drone-comb? I would rather eat it than foundation.

C. H. Dibern—They will be inclined to do so, but I should certainly use full sheets of foundation, or starters only.

Eugene Secor—They will sometimes, I think. Why not use full sheets in sections, and thus insure all worker-comb?

Prof. A. J. Cook—I think they will almost surely do so. Use full sheets unless you are willing to have drone-comb. Why not have it?

R. L. Taylor—Except in colonies having queens of the current year's production such comb would mostly be of the drone size.

Chas. Dadant & Son—They will change to drone-comb as readily if you give them a half sheet as if you give them only a narrow strip.

Rev. M. Mahin—Sometimes they will, and sometimes not. They will build less drone-comb with large starters than with small ones, or with none.

W. G. Larrabee—I always use full sheets, and have never used but a few starters; but I think they are very liable to fill out the section with drone-comb.

J. E. Pond—From my own experience I should say they would. My bees are very apt to use drone-cells for surplus storage. The reason, I think, is obvious.

C. Davenport—If there were none, or but very little, drone-comb below, and the colony had any intention of swarming, it would be apt to fill out many of them with drone-comb.

Dr. J. P. H. Brown—I have had cases where the bees would put drone-comb in the remainder. Hence, to guard against this, I fill the section with foundation to one half inch of the bottom.

Adrian Getaz—When I use small starters, the first three or four rows of cells are of normal size, then they gradually increase, and finally the drone size is reached somewhere about two-thirds of the depth of the section, and thence continued down to the bottom.

G. W. Demaree—Why should you object to drone comb in sections? When storing comb honey bees can make better headway when building "store comb"—or drone-comb—as we commonly call it. In answering your question directly, the bees will sometimes fill out with drone-cells and sometimes with worker-cells.

Texas.—The Central Texas Bee-Keepers' Association will meet at Milano, Tex., July 20 and 21, 1899. All are cordially invited to attend.
H. H. HYDE, Asst. Sec. and Treas.
Hutto, Texas.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |
|------------------------------|-----|--------|--------|--------|
| Sweet Clover (mellilot)..... | 60c | \$1.00 | \$2.25 | \$4.00 |
| Alsike Clover..... | 70c | 1.25 | 3.00 | 5.75 |
| White Clover..... | 80c | 1.40 | 3.00 | 5.75 |
| Alfalfa Clover..... | 60c | 1.20 | 2.75 | 5.00 |
| Crimson Clover..... | 55c | .90 | 2.00 | 3.50 |

Prices subject to market changes.
Add 25 cents to your order, for cartage, if wanted by freight.

Your orders are solicited.

The Army in the Drum.

A soldier sought the battlefield
Where first in coat of blue
He past before the Angel Death
In swift and stern review.
The broken swords were sheathed in mold,
The rusty cannon dumb;
But in the tangled grass he found
An army in a drum.

The sticks were gone that rattled once
Tattoo and reveille,
The shell that took the drummer's life
Had burst the head in three.
But from the shattered sheepskin rose
A low, continuous hum.
The murmur of the rank and file—
The army in the drum.

For there the bees had built a home
And stored the sweets away,
From blossoms born of soldier blood,
The mingled blue and gray.
Where once the morning sky beheld
The charging columns come,
They pitch in peace their waxen tents—
The army in the drum! —Criterion.

Trying to Keep Down Increase.

I have 47 colonies of bees. White clover has been abundant for two weeks, but it didn't secrete nectar until the last 5 or 6 days. I fenced in a square lot with barbed wire this spring, out in open ground, and moved my bees to it—about 100 yards. I never lost any by their going back to the old yard, but all in the center of the new yard are weak and haven't started work in

27A1t Please mention the Bee Journal.

the supers, while all around the outside they are well along in one and two supers, and swarming. The hives are 8 feet apart in all directions. Is it possible that the young bees get lost when playing out from the center hives, and go to the outside ones? I would like Dr. Miller's opinion on this.

I am trying a (to me) new plan to keep down increase, and get a big yield of honey. I keep all queens cleft, and when a swarm issues I cage the queen, take two supers of sections, place them on a loose bottom-board, remove the old hive, set the prepared supers in its place, take the partly-filled super off of the old hive, put it on the other supers on the old stand, take one section out of it, set the caged queen in its place, put a cover on, let the swarm return and go into the sections, let them remain that way 24 hours or longer, then go thru the old hive, cut out all queen cells and cups, take the caged queen out, replace the section, remove the swarm and super, put the old hive back on the old stand, set the 3 supers with the swarm in them on top, let the queen run into the old hive, and the work is done. It is working finely so far. I will report results later on.

RUFUS WILLIAMS.

Lawrence Co., Ind., June 7.

All Lovely in Kansas.

We are having a good honey-flow from alfalfa. Bees have doubled, and are now in supers. All is lovely in Kansas.

S. HARTER.

McPherson Co., Kan., June 23.

Love the Farm and Farm Home.

"The only drawback to any intelligent country community enjoying educational and refining privileges is lack of co-operation between the farmers themselves," writes Mrs. John B. Sims, of "Entertaining in the Country," in the July Ladies' Home Journal. "Whenever a farming community realize that in themselves lie the means of educating their sons and daughters to love the farm and the farm home, and that because one does not have the privileges of the town or large city there is no reason why he should stagnate either mentally or socially, they will have solved the problem of how to live happily and contentedly on a farm."

No Nectar in Basswood Bloom.

Basswood bloom, and almost no honey in it. Five days last week, and the apiary was quiet—allege same like graveyard.

Lucas Co., O., June 26. E. E. HASTY.

Very Discouraging Spring.

I think my bees are a little stronger than last year at this time, altho I don't remember such a discouraging spring since I came to Iowa, which was in 1871. It has been cold and rainy or so windy that the minute a bee got outside the hive to fly she was dashed to the ground.

The last winter and spring have been hard on fruit-growers in this section of country. I had one acre of strawberries winter-kill; I never had as strong, healthy plants, and I put four tons of wild hay on them for covering. Also, I had 40 cherry-trees winter-kill, some of them quite large, having been set out seven years. They were all of one kind except two, which were early Richmond grafted trees; the others were a black cherry, and were not a grafted tree. My English Morello, Montmorency, and others, came thru all right and bloomed full, but on account of rain, wind and hail, there is not much fruit set. We had hail four nights in succession.

I have a half acre of raspberries, and the bees work on them a good deal, but I have never seen a bee on my strawberry patch, altho I see such statements sometimes made in different papers. I have observed closely to see what the bees like, for I love to watch them and fuss with them, altho I can't eat honey at all. I find they work on plums,

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of **Bee-Keepers' Supplies.**

They have also one of the **LARGEST FACTORIES** and the latest and most improved machinery for the manufacture of **Bee-Hives, Sections, &c.**, that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the **BEST GOODS AT THE LOWEST PRICES.**

Send for Circular and see the prices on a full line of Supplies.

Bingham Smokers have all the new improvements. Before buying a Smoker or Knife, look up its record and pedigree.

FIFTEEN YEARS FOR A DOLLAR; ONE-HALF CENT FOR A MONTH.

Dear Sir:—Have used the Conqueror 15 years. I was always pleased with its workings, but thinking I would need a new one this summer, I write for a circular. I do not think the 4-inch Smoke Engine too large.

Truly, W. H. EAGERTY, Cuba, Kansas.

January 27, 1897.

T. F. BINGHAM, Farwell, Michigan.

Carloads of Bee-Hives.....

Sections, Shipping-Cases, Comb Foundation

and EVERYTHING used in the bee-industry. We want the name and address of every bee-keeper in America. We supply dealers as well as consumers. We have Dry Kill, Improved Machinery, 40,000 feet of floor space, and all modern appliances. We make prompt shipment. Write for Catalogs, Quotations, etc. **INTER-STATE MFG. CO., Hudson, St. Croix Co., Wis.**

gooseberries, currants, cherries, apple, raspberries, lilac, and a great many other plants, but I have never seen one bee working on strawberries.

The basswood is in bud here; I am watching to see when it opens. I shall put my supers on just before it opens, if I can. There is plenty of basswood within a range of a mile or so of me. LEWIS LAMKIN, Woodbury Co., Iowa, June 3.

Rather Severe Winter Losses.

Winter losses of bees in this vicinity were rather severe, some losing nearly all. We wintered five colonies on the summer stands, four in box-hives, and one in a dovetailed hive. All came out strong this spring, and fruit up nicely on box-elder, maple and built-up. We transferred one colony during fruit-bloom, but will wait until three weeks after swarming to transfer the remainder. We have now nine nice colonies, but they are hardly making a living at present, as clover is a failure in this section, and, should basswood be also, the surplus honey will be rather scarce, I am afraid.

My wife attends to the bees with what help I can give her at odd times, as I am busy on the farm. She has 15 dovetailed hives painted, and filled with full sheets of foundation, and supers painted and some filled with sections and starters. Better to be ready a little too soon than a little late. We use the Ideal sections with fences.

We intend having some winter-cases made to order that can be taken apart to pack away in summer. The past spring we put up a building in which to store apiary fixtures, and do the work pertaining thereto. It is 12x20 feet and 6½ feet high.

Do any of the readers of the American Bee Journal know by experience whether or not alfalfa would be a success in this (Jefferson) county as bee-pasturage? If so, what kind of land does it require?

We get many valuable hints from the American Bee Journal, and would not like to be without it.

The kingbirds are very plentiful around the apiary and vicinity, and destroy many bees. My father-in-law and myself treat them to powder and shot very frequently, and my wife also brings down a few.

A. E. MARLOW,

Jefferson Co., N. Y., June 13.

Iced Water Preferable to Ice Water.

Iced water is preferable to ice water—iced water being cooled by the ice without being brought in direct contact with it. The less ice water one drinks the better. Ice water increases one's thirst—that is, there is a greater tendency to desire drink inasmuch as ice water slakes the thirst for a moment but does not quench it.—July Ladies' Home Journal.

Bee-Keeping in Mississippi.

Not seeing anything in the American Bee Journal from this section of the State, I conclude that an occasional item might not be anything out of the way. One would think from not noticing anything from our part of the country that there were no bees here at all, but a greater mistake was never made than to draw that conclusion. A great many farmers own a small number of colonies all over our broad country, and consider they pay them very well. There are not a few apiaries on the small order all about, but some quite extensive in some localities, especially in the Mississippi Delta country.

Here in north Mississippi our honey-flows begin in April, usually, and last alternately till frost, tho with intervals sometimes of nearly a month. Our finest flow comes usually from May 3 to the 8th, on time promptly every year, with the blooming of the holly-trees, which lasts only a very few days, say 3 to 10 days at best, but during which time you never saw the like, I think. Such a roaring and busy state of affairs in the bee-yard is not witnessed, except in this very particular time. Honey can be ex-

tracted out in the yard and bees would not start robbing; this shows what it is. Some of your Northern folks may regard this with a little credulity, but if they doubt it and will come down next May, about the 3rd or 4th, they can see it verified. Yet this state of affairs lasts only till it rains, which it always does while these holly-trees are in full bloom.

We run an apiary here of 60 odd colonies, located just a mile from a large creek-bottom where these holly-trees grow; also some poplar, which yields some pretty fair honey. We have had a very light honey-flow now since holly went out of bloom, but enough has been gathered to help finish up wonderfully in sealing over the combs, etc. There are thousands of elder-bushes all over this country now in bloom, have been, and will be for some time yet, which yield nice, clear honey, and add considerably to the crop of honey.

A little later we will have peas in bloom, which yields considerable honey. The bees fairly swarm upon the blossoms. After that the summer and fall weeds and wild flowers come, which help some. Thus you see we are not without a honey-flow all along thru the summer, tho these are very light generally as compared with our spring flow. Quite a number of bee-keepers in our State produce honey by the tons. Tho we have no State bee-association, as some of the Northern States, yet in its quiet way our part of the country gathers quite a large quantity of the sweet that Dame Nature intended we should use; still there are millions of pounds of the finest honey the world ever saw wasted away every year, right here in our own State, just for the want of bees to gather it. But before locating down here, a study and examination as to locality are very necessary, as some places are no good at all for a large lot of bees, while plenty of places are good.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, June 19.—Not any comb honey on the market except buckwheat and other dark grades. We look for new crop to start in at about 13c for best grades of white; light ambers and off white 10@12c. Extracted selling at 5@7c for ambers, and 6@8c for white, according to quality, color and package. Beeswax steady at 26@27c.
R. A. BURNETT & Co.

NEW YORK, June 9.—Demand good for extracted honey, all kinds, and same finds ready sale at the following prices: Fancy, 7@7½c; choice, 6@6½c; fair, 5½@6c; common, 57@60c per gallon. Some demand for comb honey at from 11@12c for white, and 9@10c for amber. No more demand for dark. Beeswax dull at from 25@27c per pound, according to quality.
HILDRETH & SEGELKEN.

SAN FRANCISCO, June 14.—White comb, 10@10½c; amber, 7½@9c. Extracted, white, 7½@7½c; light amber, 6½@7c. Beeswax, 26½@27c. Market is firm, with very little now offering, either new or old. This year's crop of California honey is light, and there is nothing to warrant anticipating low prices the current season.

KANSAS CITY, June 22.—New white No. 1 comb 15c; No. 1 amber, 14c. New white extracted, 6c; amber, 5½c; dark, 4½@5c. Beeswax, 20@22c.
C. C. CLEMONS & Co.

CLEVELAND, March 9.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.
A. B. WILLIAMS & Co.

BOSTON, May 17.—Fancy white, 12½@13c; A No. 1, 11@12c; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7½@8c; light amber, 6½@7c. Beeswax, 27@28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is liked at this season of the year.
BLAKE, SCOTT & LEE.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11@12c; some very poor selling at 6@7c, and dull. No more business in honey before the opening of the ensuing season.
BATTERSON & Co.

OMAHA, June 2.—A few little lots of new honey from Texas have made their appearance on the market. The stock was put up by inexperienced people and only sold at moderate prices. Extracted of fairly good flavor brought 5½@6c. Comb honey put up in 60-gallon cans and filled with extracted sold at 6½c. This is a most undesirable way of packing comb honey. Trade does not care for it.
PEYCKE BROS.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10@11c; dark and amber, 8@9c. Extracted in fair demand without change in price. Beeswax, 25@26½c.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey.
M. H. HUNT.

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

Introducing Queens—A Certain and Practical Method.

BY W. Z. HUTCHINSON.

TO introduce a queen to a colony of bees, two things must be well considered—the condition of the bees, and the condition of the queen. The condition and behavior of the queen are very important. If the queen will only walk about upon the combs in a quiet and *queenly* manner, and go on with her egg-laying, she is almost certain to be accepted if the other conditions are favorable. Let her run and “squeal,” and utter that peculiar “zeep, zeep, zeep,” and the bees immediately start in pursuit.

To introduce a queen from one colony to another in the same apiary does not call for the skill needed when a queen has been absent several days from a colony, and is jaded by a long journey. I have frequently taken a queen from a colony, and caged her to send away, and then immediately taken a laying queen from a nucleus and placed her upon the spot upon the comb whence I had removed the other queen, and had the satisfaction of soon seeing her surrounded by a circle of admiring retainers. I believe that there are times, particularly when honey is coming freely, when a colony with a laying queen would accept *another* fresh laying queen, simply by having her placed upon the combs; and all would go well until the queens came in contact.

So far as the queen is concerned, it is important that she be brought before the bees in a natural manner, in such a place and way as they would expect to find her. When queens have come from a distance they are more difficult to introduce. For the purpose of introducing such queens, the old Peet cage was excellent. It was a poor shipping-cage, but, as an introducing-cage, that could also be used as a mailing-cage, it has had no superior. As an introducing-cage it did have *one* objection, and that was that the bees might liberate the queen too soon; that is, before they would accept her. It is possible, however, to use such a cage that this objection may be overcome, but the cage cannot be used for a mailing-cage. This is another illustration of the fact that these combination tools are seldom so satisfactory as special tools.

The style of cage, and the method of using it, that I am about to describe, are not new. I think that Mr. Doolittle has used and described this cage. Mr. F. Greiner, of New York, also described it in *Gleanings in Bee-Culture* for Oct. 1, 1898; and I have to thank that periodical for the use of the cuts that appear in this article.

The cage is made as follows: From a piece of ordinary wirecloth, 6x8 inches square, a piece 1 1/4 inches square is cut from each corner. Each side and end is then raveled

out to the depth of 3/8 of an inch. The result will be a piece of wirecloth looking something like Fig. 2. The sides and ends are bent up at right angles, making a tray-like cage 1 1/4 inches deep, 3 1/2 inches wide, and 5 1/2 long, looking something like Fig. 3.

To use this cage in introducing a queen proceed as follows: First remove the old queen from the colony to which the new comer is to be introduced, then look over the combs until one is found upon which the bees are gnawing out in considerable numbers. Shake and brush the bees from this comb. If the circumstances are such that the comb can now be carried into some room, so much the better, as it prevents any possible loss of the queen by taking wing. If she is clipped, of course this precaution is unnecessary. Place the open side of the cage against the face of the comb, choosing such a spot that the cage will cover a place where young bees are emerging. It might also be well to include beneath the cage a little unsealed honey, altho Mr. Greiner says that this is not necessary, as the bees will feed the hatching young as well as the queen. There certainly can be no harm in allowing a little unsealed honey under the cage. Remove from the shipping-cage all of the escort bees that came with the queen. With the queen alone in the shipping-cage, open one end, and place the open end under the wirecloth cage, raising one end of the latter for this purpose. Watch carefully, and as soon as the queen leaves the shipping-cage draw it out and press down the wirecloth cage, thus caging the queen against the surface of the comb. Press the cage into the comb until the ends of the wires at the sides and ends are firmly embedded in the septum or midrib of the comb. This must be done care-

fully, yet thoroly, or the bees may undermine the cage and kill the queen before the time comes when they would accept her.

In replacing the comb be sure that sufficient room is left so that the bees can pass between the cage and the adjoining comb. The queen will soon have a retinue from the newly-hatched bees that are ready to accept her, as they have never known any other queen. She will soon begin laying in the few cells that are at her command, and when she is released will be in nearly a normal condition, and surrounded by quite a little band of loyal followers.

In three or four days, if a fine escort is found hatch

out under the cage, and the outside bees are seen to be feeding the queen thru the wirecloth, the cage can be gently removed, and the comb put carefully back in the hive, and there is no question but what the queen will be accepted; in fact, she has been accepted before she is thus given her larger liberty.

If the bees are seen to be angry towards the queen, clinging to the cage like so many burdocks, look thru the hive for queen-cells, destroying every one. Keep the queen caged until all of the brood is sealed, then destroy every cell before releasing her. Now that all possible hopes of rearing a queen of their own are gone, they will accept the inevitable. Not one colony in one hundred will drive you to this last resort; but you are master of the situation if you follow these instructions.—Bee-Keepers' Review.

Handling Bees—Suggestions for Beginners.

BY C. P. DADANT.

A BEE away from home, or laden with honey, never volunteers an attack. She acts only in self-defense when closely prest. This axiom is so well established, and so well known by apiarists, that if I were not writing mainly for beginners, I should not think of mentioning it. Thus, in order to render bees harmless, it is only necessary to cause them to fill themselves with honey, and this is done by frightening them with smoke. When smoke is driven into a hive thru the entrance, the bees at once begin filling themselves with honey. But with them as with human beings, it is the most experienced that are the slowest to take fright. So when the old bees are all at home it is more difficult, and takes more time, to compel them all to fill themselves. For that reason it is much safer to handle bees during the warmest part of the day, or at a time when the greater part of the old bees are in the field. The bees which compose a swarm are usually filled with honey for the journey that they expect to take, and are harmless, unless crushed or very much irritated by the anger of others, and the smell of the poison.

It is not absolutely necessary to smoke a colony of bees till all the bees fill themselves with honey, in order to handle them safely, but it is certainly the safest method. An expert may open a hive without smoke, and without danger, and may handle the combs and return them to the hive without getting a single sting by being quiet, steady and fearless. The Italian bees especially may often be handled without risk in this way, for they are quieter than most other races. But this method is hardly to be recommended for practical usage. It requires too much caution, and there is too much risk to run. A combination of the two methods—using a little smoke to frighten the bees whenever they show signs of irascibility, yet handling them with as little disturbance as possible—is most advisable to practical apiarists. But the one who has no fears, and handles his bees without smoke, may often cause others to be stung.

I have a friend in a neighboring city who owns a dozen colonies of bees. He had been in the habit of handling them at all times of the day, and without preparations. He told me once that his neighbors complained of his bees stinging them, and were talking of putting a complaint against him for keeping a nuisance in the city. "Yet," said he, "my bees are very quiet, and I never have to use smoke."

I accompanied him to the hives, and he opened one to show me their condition. One or two bees buzzed around my head, and I prudently retreated a few steps, for I am not at all proof against them. But he continued his investigation. After he had closed the hive I suggested that his bees were not so quiet after all, and that perhaps if they did not sting him he was in part responsible for their stinging the neighbors. I advised him to act with them just as if he were afraid of them, using a smoker and all ordinary precautions, and from that time on he had no more complaints from the neighbors.

It is a fact that the fearless apiarist may often be entirely unharmed, while others several rods away may be stung by the very bees which his manipulations anger. His quiet, determined demeanor is his safeguard, while the uninitiated strikes at the angry bee and dances till he is stung.

When you wish to open a hive of bees, if you desire to be perfectly safe, arm yourself with a smoker, cover your head with a veil, and step boldly to the front of the hive; send smoke thru the opening for a half minute, then stop and repeat the operation after another half minute, or until they make a steady hum, which will show that they have

given up the desire to fight. Then open the hive, smoke again gently, and you may lift the combs one after another, shake bees on your hands, in fact, handle them like harmless, inanimate things, provided you do not press any of them too hard. Avoid quick motions, do not breathe upon them, and if there are other bees flying about in search of plunder, do not leave the hive open too long. In case of accidents the smoker should be used freely, and it ought to be at hand for any manipulation in the apiary.

It is much easier to prevent the anger of bees than to put a stop to it after it has begun. If you mismanage a colony of bees and rouse their anger, it is quite likely that this disposition will remain with them for days, for weeks, for months. A colony which has been thoroly angered may retain this ill disposition for a long time. Even if smoke is used in the manner prescribed, it becomes of no avail for a portion of the bees that seem to remember former treatment, and that simply remain passive until the smoke is cleared off, and the enemy in full sight, when they pounce upon him with a will. As I said in a previous article, cotton clothing is better than wool, and all irritating causes should be avoided. Mischievous boys who delight in poking sticks into the entrance and running away, cause more stinging than a whole season of careful management and handling.

We always use a veil fastened to the hat, and this may be slipt on or folded in the crown of the hat as occasion requires.

Gloves are not practical. A careful person will handle the bees so that a sting on the fingers will be rare, and the clumsiness caused by gloves will cause fully as much danger as there is in manipulation with the bare hands.

The most important instrument is the smoker, and the best smoker is the muzzle-loader. In guns, the breech-loader is a great improvement on the muzzle-loader, but in smokers the reverse is true. The fire must be at the bottom, at the farthest point from the nozzle, and the refilling must be on top of the coals. With a breech-loading smoker you must either unload your smoker from time to time, to fire up again, or you must put the fuel under the fire instead of over it. This is obvious. With a good smoker, after the first lighting, the fire need not go out for the entire day, if you have a whole day's work at the bees, provided you refill it with fuel as needed, and you may even leave it sitting up during the entire dinner-hour, with the certainty of finding it ready for use when you return. It is not the purpose of this article to recommend any one kind of smoker, there are half a dozen makes sold, and constantly improved for the convenience of the public. Hancock Co., Ill.

Bee-Keeping as a Specialty—Other Matters.

BY MRS. L. C. AXTELL.

IT seems to me that to throw out the thought that a person can do well and prosper in life with only bees as a business is misleading, and is doing damage to the industry, as there are so many years that the honey crop is short, that persons depending wholly on bees for a living will sooner or later give it up with disgust.

Most of those who make it a specialty, make a part of their living by writing for the bee-papers, or by lecturing on bees, or something else, rather than merely keeping them for what honey they gather. Those contemplating going into the business as a specialty are young people and beginners, many of whom, if not the greater part, would not succeed as specialists.

The bee-business with farming will pay well; the bees will help pay for the farm, much of the bee-work can be done in the winter, and it is something that the whole family—father, mother, and all the children—can work at from January to January, and during the hurried months of farming there need be but little left to be done with bees except what the women-folks and children can do, unless there are many colonies.

STRAWBERRIES AND BEE-KEEPING.

These go well together. If the strawberries are properly cultivated there never need be a failure, and they ripen and are gone before the height of the honey crop, only the later ones lap on swarming-time.

POULTRY AND BEE-KEEPING.

The poultry business, too, goes well with bees. They are a steady profit one month after another, and so are hardly appreciated as they should be. Many make a failure

with poultry by trying to keep too many. They reason that because a few pay, a good many will pay better. But if a few are kept of some pure breed, that will pay for selling both poultry and eggs for hatching, besides what is sold to the butchers and grocers, they will help along nicely, more than they get credit for.

I see no reason why all the above might not be combined with bee-keeping, and other industries besides. I think it not best to keep "all the eggs in one basket," so if one fails somewhat others will not. True, some years some may be more neglected than they should be.

It does not cost much to keep bees after one has them, and when they fail to get honey let them alone, only see to it that they do not starve out. Many who keep only a few bees take away what they can get at such times, and fail to feed back if needed, and so let the bees starve out. Perhaps the very next year they would have paid their owner largely if they had not been robbed. But if they have barely enough to keep them alive, bee-keeping, like all other industries, does not pay. We should not keep more bees than we can care for, nor more than will do well in our locality.

Carpenters, merchants, dressmakers, seamstresses, and school-teachers, it seems to me, might all keep a few colonies of bees and make them profitable, and find much enjoyment and health in caring for them. Especially those who are much confined to the house would find it a real recreation if they would begin with the right kind of a hive, gentle bees, etc., and face well protected from stings. There is so much that is interesting in their habits that they will soon learn to love to work with them.

BEEES FOR THE CHILDREN.

The neighbor who is wise enough to devise plans to make his children love home gives each one a calf and a colony of bees, from the oldest to the youngest, if he will care for them. It is interesting to see how they watch father care for his bees, and how gladly they help him, so he will help them back, and so care for their bees. When they get stung they try to bravely bear it, and when they get homes of their own, it will cost them but a trifle to begin bee-keeping on a larger scale. The calves become their playmates, and make them love home all the more—to think they own something themselves.

BEEES FOR HIRED HELP.

A few years ago I had a young girl working for me, helping at housework and bee-work. She bought a colony from us, and paid for it in work, took it to her father's home (about six miles away, as there were not many bees, and it seemed to be a good location for them.) They did well for her; she learned from us how to care for them, and would go home occasionally and put them in order for each season of the year. I do not know how much honey she got, but quite a considerable, the most of which she gave to her parents, but she married in two years or so, and sold her bees for \$30, having increased them to six colonies. The \$30 was quite a little help to her in buying her bridal outfit, as her parents were quite too poor to assist her much. I think a wiser way would have been to have held on to her bees, to have taken them to a home of her own, and to have been married in a calico dress rather than part with her bees.

Many localities change from being good for bees to being poor, by being highly cultivated, and crops raised that yield no honey. That is partly the case in our neighborhood; all low lands and heads of slough are tiled, and corn and other crops raised, so that little room is left for Spanish-needle and wild flowers. Warren Co., Ill.

Planting for Honey—Buckwheat, Etc.

BY F. A. SNELL.

IN addition to the farm crops that are valuable for both stock and grain, we have only one more to name for our section of country, or our latitude, that is also valuable as a honey-plant, and that is buckwheat, which affords a good yield of both grain and honey when conditions are favorable. We have three varieties of this—that known as Japanese, the silver-hull, and the common. I have grown each variety, and for a grain crop the Japanese has proved to be superior, as it has given the largest yield. For the honey crop either produces well in good seasons.

Buckwheat is the only crop that we plant for a fall

honey crop. This crop is, as a rule, profitable to the farmer bee-keeper. Even if no surplus honey is secured from it, enough may be gathered by our bees to keep up brood-rearing, which is of great importance, especially where fall flowers are otherwise scarce. As I have said in another place, successful wintering depends very largely upon having a strong force of young bees with which to go into winter.

I omitted in my list of honey-producing trees the locust, which yields well in honey, and is valuable for timber also, but with us the borers ruined our groves some years ago, so that its planting has been dropt. The few trees remaining bloom each season profusely, coming in a little before white clover. In sections where the tree will thrive, no doubt it will pay to grow it. One objection to it is, it is hard to rid the ground from it after once established.

I am prompted to write what I have on the subject by a realization of the fact that we cannot do too much in planting to increase the honey-flow, and the sooner we as bee-keepers realize this and act in this direction the better. In the list of trees, bushes and plants named in these articles, I have named only those that produce for the apiarist at least a double crop or harvest, either of which will pay well for time and money invested, and add to the value and beauty of many a home if the suggestions made are carried out.

The amount of fruit that may be grown on a plat of two acres with good care is almost surprising. Planting of cherry, plum, apricot, quince, peach and pear trees may be made at a distance of 15 feet apart each way, and will allow 205 trees to an acre of ground. Apples planted at a distance of 20 feet each way will give 110 trees to the acre. Any small fruit, such as raspberries, blackberries, strawberries, currants, gooseberries, etc., may be planted in rows a suitable distance apart between the rows of fruit-trees, and will soon come into bearing, and pay good rent on the entire plat put out. These returns will come in the second year, and will in addition to rent return pay for all labor given, if good culture is given, with most of the small fruit named.

In a few more years the trees will come into bearing, and it is useless to give here the value in dollars and cents that the crops secured will be worth. It is self-evident to all thinking people that such an investment would be a good one for any painstaking person. There is another consideration in the matter above dollars. We would be adding beauty to our home surroundings, and health to ourselves and families, as well as be doing a good work for posterity, thus proving our devotion to home and country, as becomes every true patriot.

Much more could be written in advocacy of planting to secure honey, fruit, etc., but I think the above will suffice, and if only a few follow the suggestions or thoughts advanced by me, my feeble effort in this direction will not have been in vain. Carroll Co., Ill.

Mr. G. M. Doolittle's Queen-Rearing Methods.

IN response to a question in *Gleanings in Bee-Culture*, as to whether Mr. Doolittle has made any advanced steps over those taught in his book on queen-rearing, he replied that he had nothing newer than what is contained in his "Scientific Queen-Rearing," the remarkable feat of securing 600 sealed queen-cells from one colony, the queen laying all the while, having been accomplished by simply following the instructions laid down in his book. Going into details, he said:—EDITOR.]

When spring opens I select one of the strongest colonies I have in the yard, and one having a queen reared the summer before, as I wish one which is not liable to fail in her egg-laying powers before the season is over, as that *laying* queen below has very much to do with queens of the best quality, in my opinion.

About the 10th to the middle of May I go to several hives till I find the number of combs of sealed brood that are necessary to take the place of those having no brood in them in the hive I have selected, which is generally from two to four. These combs of brood (without bees) are now set in the hive, when in a week or ten days I have a colony strong enough to commence operations. Perhaps I should say just here that I use nine Gallup frames in this hive, which is a *chaff* hive, and that I bring from my out-apiary, the fall before, the queen to rule over this hive, which is a mismated (or "hybrid") queen, as generally called, for I

find that hybrid bees, showing about as many black bees as those with yellow bands, will build and complete nearly double the number of cells as will pure Italians, and seem to take to this line of work better than any other. I usually bring several queens of this class to take the place of those sold, and then select the strongest colony having one of these queens. As soon as the selection is made the rest are used in the out-apiary again. I tell this only as I wish to give everything just as I do it.

As soon as the colony is strong enough to go into the upper story, I take two combs from below, having *mostly* eggs and unsealed larva in them (don't take any drone-larva, as drones above a queen-excluder are always a nuisance), and in their places put two combs of sealed brood from other hives, as we wish all the bees possible thus early in the season.

I now put on top of the hive a hive having a queen-excluder *nailed* to its bottom (if thus nailed we never have to touch the excluder if we wish to remove the upper hive during the season), as it always comes off with the upper hive, and in the center of this upper hive put the two combs of brood, four frames well filled with honey, a division-board feeder, and two dummies made from inch or 7/8 lumber.

When about two days have elapsed for the colony to adjust itself to the new conditions, it being fed about a pint of *thin* sweet every night, if honey is not coming in from the field, they are ready for a batch of prepared cell-cups, as given in my book. To tell all about how to prepare these would be too long for this place; but all can find all about the matter by turning to chapter 7 of the book, and I could not tell that part any better were I to try it over again.

Before going for the royal jelly and the larva to transfer into it, I stop at the hive, take out one of the dummies, shove the frames that way till I leave a frame's space between the combs of brood, when the cover is put on. As a rule it takes me from 15 to 20 minutes to get the royal jelly, the larva, put the jelly and larva into the cell-cups, and get the now prepared frame to the prepared hive. I now remove the covering (which is a quilt, with a 4-inch sawdust cushion over it, and a hood or cap 8 inches deep over all), when I find the space left for the prepared frame completely filled with bees—so much so that I have to work the frame slowly up and down in lowering it, so as to cause the bees to run out of the way. I don't know that causing the bees to cluster in this vacant space between the frames of brood has anything to do with the matter, but it has always seemed to me that they are better prepared with royal jelly and for queen-rearing by doing so.

Three days later I go to the hive again, take out the other dummy, draw the frames to the side of the hive until I come to the first frame having brood in it, when I lift the frame of cells, take off one or two of them, for the royal jelly needed to start the next "batch," when the frame of cells is placed in the vacant space behind the frame of brood, caused by taking out the dummy and drawing the others along, thus preparing the same place for the next frame of prepared cell-cups which the first one occupied, and when all ready it is placed there as was the first. Three days later a frame of honey is taken out from the opposite side from which the last dummy was taken, the frames again drawn along till we come to the frame of brood, when the last prepared frame of cells is taken out, one or two taken off for royal jelly, and the frame "jump" to the outside of the frame of brood, which gives room for the third prepared frame between the frames of brood again, where it is placed as soon as prepared.

As I do not work with the bees on Sunday, I time it so that no cells have to come off that day, and so four days now elapse before I put in another prepared frame, which makes ten days from the time we started, so that we really have only three prepared frames every ten days.

I now take out the frame of "ripe" cells, or the first one prepared, and distribute them where wanted, getting the bees off, etc., as given in chapters 8 and 9 of the book, when I lift out the two frames of brood, look them over to make sure that the bees started no queen-cells on these frames (unless this is done we *may* have a queen hatch when we least expect, and destroy all of the cells on the other prepared frames), when these two frames of now sealed brood are "jump" over behind the two frames of cells now remaining. I now take out a frame of honey on each side, and all the frames along toward either side of the hive, so as to make room for two frames containing eggs and larva taken from any hives in the yard (generally from nuclei when under full headway later on), which are placed in the center of the hive again, as the first two were,

being left apart for the fourth prepared frame, which is now fixed as was the others, and put in.

Onondaga Co., N. Y.

G. M. DOOLITTLE.

[We mail Mr. Doolittle's book, "Scientific Queen-Rearing," for \$1.00; or we club it with the American Bee Journal one year—both for \$1.70. Every bee-keeper who gets it will be fascinated with the way in which Mr. Doolittle tells his story of rearing queens. And, besides, the reader will learn just how the "king of queen-breeders" does it.—Ed.]

Queen Insensible by Cold Still Valuable.

BY W. W. M'NEAL.

NOW here is to those who say a queen-bee is "no good" after having been rendered insensible by cold:

Last winter, a little time previous to the cold spell that began in the latter part of January and closed Feb. 15, I had a number of nuclei containing choice queens to be used in cases of emergency, and for replacing inferior queens in full colonies when the bee-season opened. Well, upon passing thru the apiary one cold day toward evening, I tapt on several of the small hives to see if the bees were still alive; they all responded but one. I did not open the hive then, but waited until in the afternoon of the next day. When I opened it the sun was shining, but the wind was blowing and the air cold. The bees were apparently as dead as they could be. I lifted the combs from the hive and stood them in a sheltered place from the wind where the sun could shine directly on them and the bees. In a short while I saw signs of life, and most of the bees with the queen were soon able to crawl about on the combs. Many of the bees, as I have often before witnessed, had crawled into the cells in a compact mass, whether in a vain endeavor to keep warm or in sheer desperation from hunger I do not know. But upon becoming sufficiently warmed they bacted out of the cells and partook of honey ravenously. If I mistake not, a bee that dies solely from starvation always has the tongue extended.

I constructed a still smaller hive for the remaining bees, and after getting them into it, I carried it into the house, where it remained for several days on the mantle-piece close by the fire in the grate. Then it was I noticed a queen lying at the entrance of a hive containing one of my best colonies. I waited till dark, when by the aid of a lantern and a smoker I made an effort to get the little colony into the large hive by way of the entrance. I might add that the weather at this time had moderated somewhat, tho I did not care to break the covering to the hive.

The bees of both colonies fought till I believe every bee belonging to the smaller one—excepting the queen—was killed. I also feared that possibly the large colony contained a young queen and it was the old one I had found at the entrance. But if they did I was never able to find her, tho I took special care to clear the ground in front of the hive that I might see a queen, if she were carried out by the bees. And, besides, the queen introduced was so marked as not to be mistaken for another. This queen is now the mother of a powerful colony of bees—worker-bees. I believe it has been claimed that such queens lay only drone-eggs.

Scioto Co., Ohio.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 50 cents; 50 for 70 cents; 100 for \$1.25; 250 for \$2.75; 500 for \$4.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

Yellow Sweet Clover is of more value than the white, according to John Weir in the bulletin of Kansas University, as it blooms six weeks earlier, and at a time when forage is scarce.

Boiling Foul-Broody Honey Three Hours, Editor Doolittle, in the *Progressive Bee-Keeper*, thinks unnecessary, and he speaks of thousands of colonies "being cured by having 'scalded' foul-broody honey fed back to them without their ever having the disease again during the years between 1850 and 1890."

Carelessness in Uncapping is charged by the editor of *American Bee-Keeper* as a fault in a number of apiaries he has recently visited. He says: "If we would preserve the even surface of our combs, essential to rapid and satisfactory work with the extractor, it is important that every cell be uncapped, and the frames accurately spaced when returned to the bees."

Egg-Laying Capacity of Queens.—Chas. Dadant figures in *Gleanings in Bee-Culture* that Mr. Doolittle's favorite hive, the Gallup, "has room for but 2,400 eggs per day, while a good queen can lay more than 3,000 eggs daily." Mr. Dadant found by actual measurement of comb surface that several good colonies had 70,000 to 80,000 cells in each occupied with eggs and brood, making 3,300 to 3,800 eggs laid daily.

Precaution Against Foul Brood.—One of the best precautions against foul brood, according to M. Bertrand, editor of *Revue Internationale*, is to keep the colonies strong and in healthy condition. While the disease does not appear spontaneously, a weak or diseased colony is a much more promising field for the growth of the germs than one that is strong and healthy. As it is good practice on other accounts to keep only strong colonies, his advice will commend itself to practical bee-keepers.

Foul Brood had considerable discussion at the Ontario convention. Some thought the hives should not be used again without boiling or other special treatment, but Inspector McEvoy was very emphatic that the hive needed no treatment whatever. Askt how long honey taken from an infected colony should be boiled before it was fit to feed to bees, he said: "I never recommend it at all from the first summer, because I couldn't trust the people. I have never had any trouble when they put half water with it and bring it to a sharp, bubbling boil."—*Canadian Bee Journal*.

Behavior of Swarming Clipt Queens.—In the *Australian Bee-Bulletin* the following question is asked: "Suppose a queen with her wing clipt leaves a hive with a swarm and there is no one about to hive the swarm, will the queen never go back to the hive if left alone?" The answers vary somewhat. One says she will return with the swarm if the grass is thick, and six or eight inches high. Another that she'll return four times out of five, but will come out day after day until the young queen emerges, when she will be no more. Another that she will generally be found several feet or yards away with a ball of bees. But one man thinks that a clipt queen which issues with a swarm never re-enters the hive. In this country she can be relied upon to get back in most cases if she can.

On the Poison of Honey-Bees.—The poison drop, freshly excreted, weighs from 0.0002 to 0.0004 gm. It has a specific gravity of 1.0013, is clear as water, and has a marked acid reaction, bitter taste, and a pleasant, aromatic odor. The poison was obtained by collecting the drops, or by extracting the entire poison apparatus with alcohol. This caused coagulation, and the poison was taken up by the alcohol. When the alcohol was supersaturated with ammonia and evaporated, a yellowish material was obtained. Solutions of this gave reactions of formic acid. The author's investigations, however, showed that formic acid

does not possess the poisonous properties of the bee-poison. The solution of the poison contains an albuminoid, hydrochloric and phosphoric acids, sodium and calcium. The albumin does not produce the poisoning, since a solution of the poison freed from it produced poisoning symptoms, as observed on the conjunctiva of a rabbit's eye. Evaporating the poison and heating at 100 degrees does not diminish its properties, nor does keeping it for some time in sealed capillary tubes. On the other hand, when kept in open glass tubes the poisonous properties are lost in about four weeks. The poison spoils on standing, and loses its toxic properties. The poisonous substance is held in suspension by acid, and can be precipitated by alkali. This shows that the active principle secreted by members of the aculeata group of Hymenoptera is a base.—J. Langer, in *Experiment Station Reports*.

Section-Cleaning Machines that give entire satisfaction do not seem to be as easily within reach as at first was supposed, altho there is little doubt that the section-cleaning of the future will be done by machinery. Editor Root in *Gleanings in Bee-Culture* says the solid disk sand-wheel is not a success, because it fills up with propolis, altho Mr. Golden claims good work with a sanded belt. The Aspiwall machine is fitted with knives, and does not clog, but Mr. Root says he has not yet been able to do as smooth work with it as by hand. Perhaps the machine heretofore described on these pages by C. Davenport may be as good as any.

Thick or Thin Combs for Extracting?—In the discussion reported in *Canadian Bee Journal*, the general opinion seemed to be that there was an advantage in the thick combs because the cappings projected out past the frame, making it easier to uncap; but Mr. McEvoy went so far as to have some combs $1\frac{1}{4}$ inches thick, and didn't like them. The Hoffman frames were troublesome about uncapping, because the shoulders stuck out in the way. Mr. Armstrong said the Hoffman shoulders would not be in the way if the comb was built thick enough. Mr. Darling said the thick comb bulged the screen in the extracting-basket, and so it might get out of place.

Foul Brood Needs Severe Treatment.—In *Gleanings in Bee-Culture* appears the same picture of foul brood that appeared some time ago in this journal from a photograph by Thos. Wm. Cowan, and referring to it Editor Root says: "If I had combs as badly diseased as the one shown in the illustration, I would burn them at night if possible, and then bury the ashes below the reach of a plow or spade. In the light of our present knowledge of the difficulty of killing the spores of this enemy at a boiling temperature, I would never think of extracting foul-broody honey. I would count it as profit and loss, and consign it all to the bonfire, combs and all."

Growing Basswoods from the Seeds is reported by A. I. Root as a rather difficult thing, and he asks in *Gleanings in Bee-Culture*: "Can anybody tell us how to get 50 percent, or even 25 percent, of the seeds to germinate?" He has sowed the seeds at almost all times with almost no success, but in some cases the seeds came up readily of themselves without any sowing. A peck of seed was drilled in upon four rods of ground, but not a dozen trees came up the following spring, and the bed was sowed with asparagus. He is convinced that basswoods grow with much more vigor on very rich ground, especially that which has been manured for many years, so that it is old, black, and rich. On such ground he has had little trees grow three feet high the first season.

Suppression of Swarming is satisfactorily secured by R. Pincot, as reported in *Le Ruches Belge*, by taking away all frames of brood except two containing mostly eggs and young brood. This is done when preparations for swarming begin in the way of starting queen-cells. All queen-cells are carefully cut out from the two frames of brood that are left, and the bees brushed from the combs removed, abundance of super room being furnished. The combs of brood thus removed from several colonies are put in empty hives, eight frames of brood in each hive, all queen-cells carefully cut out, then a colony of medium strength is removed from its stand and a hive with its eight frames of brood put on the stand. A young laying queen from a nucleus is put in the hive caged, and liberated two days later. After practicing this plan for two years he thinks well of it.

CONDUCTED BY

DR. C. C. MILLER, *Marengo, Ill.*

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Probably Superseding the Queen.

I have a prime swarm of black bees, hived June 9, that insist on storing queen-cells at a lively rate, something I have never seen before. What is the matter with them? I have been cutting them out as fast as they build them. Is that right?

ILLINOIS.

ANSWERS.—The bees probably want to supersede their queen. If you would keep close watch of the matter you would probably find that about one out of three of your swarms supersedes its queen some time after swarming. In other words, every queen, in the normal course of affairs, is superseded before she dies, and altho occasionally this superseding may be before swarming-time, it is usually after. If queens average a life of three years, that makes about a third of them to be superseded every year.

Separating Wax from Honey.

I have bought several hundred pounds of "chunk honey" from the farmers here, and wish to separate the wax from the honey.

1. How can I render it in the most economical manner, and with the least trouble?

2. If in the solar extractor, how shall I make it so that the hot sun will not injure the honey in melting the wax?

GEORGIA.

ANSWERS.—1. Probably the solar extractor will fill the bill as well as anything.

2. Partially shade the extractor, so there will be merely heat enough to melt. Perhaps a thin cloth hung over will effect it. By a little experimenting you will settle on the right thing. It may be well to empty the extractor frequently, for the long-continued heat is bad for the honey. Pour out the melted wax and honey, and let it cool and separate outside the extractor.

Queen Flying After Introducing Drones Flying Before the First Swarm.

1. I sent for an untested queen and put her into a small hive with hatching brood, and in a week or two I let the bees out, and in a day or so more I saw the queen out flying around. She kept on for a week. Why?

2. Do drones hatch out and fly before the first swarm issues?

NEW YORK.

ANSWERS.—1. I don't know. Sometimes a nucleus with a laying queen will swarm out for no apparent reason except the weakness of the nucleus, but they don't usually go back so many times. If the queen was unfertilized the bees might have gone with her on her wedding-flight.

2. Oh, yes; drones may fly out, plenty of them, long before any swarm. Indeed, you are not likely to see a swarm without plenty of drones first.

An Unusual Case of Swarming.

Did you ever have an experience like this? June 14 I hived a very large swarm of bees in an 11-frame dovetail hive. A neighbor indicated the hive she thought the swarm came from, and altho I thought there were a large number of flying bees for a colony that had cast so large a swarm, I removed the old hive to a new stand, and put the new one in its place that evening. At noon the next day the hive was so crowded that I put a super on it, which before night

was full of bees. On the 18th (Sunday) I hived another very large swarm, and in looking to see if I could find where it came from (I was not out when they swarmed), I discovered that they undoubtedly came from the colony hived on the 14th. I thought of course they had swarmed out, but on examination I found a good, fair-sized colony left in the hive, four frames of eggs, six or eight of them in queen-cells. They were hived on 11 full combs. COLORADO.

ANSWER.—No, I never had an experience of the kind, and altho I think I have read of such a thing it is *very* unusual for a swarm to send out a swarm four days after being hived. It is quite possible that you made a mistake as to the colony from which the first swarm issued, and as in that case you would put the swarm in place of a strong colony that had not swarmed, your swarm would be very much stronger than if you had put the swarm in the place of the colony from which the swarm had issued.

Small Bee with the Hive-Bees.

I see a small bee working with regular worker-bees, not over half their size, or considerably smaller than the smallest young bees of the hive. An old bee-keeper I askt about them says they deposit their honey in a mullein-stalk, and that they have a sting. They are about the color of a hybrid, or nearer the color of Italian than the black bee with (not bright) yellow bands. Do they die out every year like wasps?

MASSACHUSETTS.

ANSWER.—You say you see them "working with regular worker-bees," but that may mean in the hive or out of the hive. If you mean they are in the hive, then they are dwarfs of the regular hive-bee, made dwarfs, probably, because the comb in which they were reared was bent or crowded in some way so that the young bees in the cells hadn't room enough. Such a thing may happen on rare occasions in any hive, and no dwarfs afterward be found in the same colony.

If you mean you see them working with regular working-bees out on the flowers, then they may be wild bees, of which there are a great many kinds. Most of them have stings, and die off like wasps and bumble-bees, a fresh colony being started in the spring with a single female bee.

Smoking Bees—Large Colonies.

1. As my bees are very bad fighters, shall I smoke them at the entrance, or how, as the brood-chamber is above two supers with the frames, and I will have to lift it off to get the two supers away from under it?

2. Do you smoke bees from the entrance in removing sections from the super, or do you smoke from the top?

3. I took off 39 pounds this week, of as nice and clean white clover honey as you ever saw. My bees are working on the blossoms of the cigar tree, and also on the leaves of the mulberry trees. We have plenty of white clover yet, and sweet clover is just coming into blossom nicely. Last season I had one of my hives to cast the largest swarm I ever saw, and I put them back into the parent hive; they have filled two supers with eight frames and are working nicely in two supers with sections. Would you advise taking away the two supers with the eight frames now, or later on in the fall?

4. I have kept my bees from swarming by entrance-guards in front and by returning the swarm to the parent hive, and giving them plenty of room in the supers. I do not know how the brood-chamber is on any of them, as my bees are so cross I cannot handle them without they go for everybody around the place, even for the chickens (my hives are on a bench two feet from the ground) so I do not bother them any more than I can help. My father's bees are very gentle (and my bees are the swarms from his colonies), and his can be handled any way even by me, so I do not think it my fault on account of hard handling, as I am very careful. My father keeps his bees in the city, which may account for their gentleness.

5. What is the price of a bee-escape by mail?

6. My father allowed one of his colonies to swarm today, because he thought there were too many bees in the hive. Don't you advise keeping them as large as possible, and get better results in the sections? I told him I thought so, any way, from what I had read. MARYLAND.

ANSWERS.—1. From what you say about your bees, the probability is that you may need to give them smoke wher-

ever there is a chance for it. However, if you go at it in the right way, you may not find they need so much more smoke than your father's. Perhaps the reason yours are so much worse to handle than his is because they are handled less. If bees are where people are constantly passing they seem to get used to it. First blow a few puffs in the entrance, not more than two or three puffs of smoke. Then you will probably lift off the super of sections. Pry it up a little at one end, and blow in a little smoke there. Then lift off the section-super and blow smoke over the brood-chamber. Then pry up one end of the brood-chamber, and blow a little smoke in the opening, if they seem to need it, and some more over the supers that are under, after you have lifted off the brood-chamber, when you can lift away the supers from below. But don't be surprised if you find little but brood in the supers that are below.

2. You will smoke about in the same way when taking off the super of sections. First a little smoke at the entrance, then raise the cover a little and smoke, then smoke over the whole top of the super before removing it. Indeed, you may give a good deal of smoke over the top of the super before taking it off, so that a large number of bees will run down out of the sections, but if you pour in too much strong smoke the honey will taste of it. In subduing bees with smoke, be guided by their actions. When they show that they are ready to give up and get out of the way, then let up on the smoke business. If they show fight, give them a little more smoke. It's useless and cruel to smoke the poor things when they don't need it.

3. If there is only honey in the two 8-frame supers, it matters little whether they are taken away now or in the fall. If they contain brood and very likely they do then you will do well to leave them till fall.

4. Don't carry that entrance-guard business too far. It will be all right so long as the old queen is there, and may do for a time after, but you may count on the old queen being put out of the way in a week or 10 days after the issue of the first swarm. Then you have virgin queens to deal with, and when it comes time for the one in the hive to be fertilized, she must be allowed to fly out or she never will produce anything but drones.

5. The price of a bee-escape by mail is 20 cents.

6. Yes, it is generally supposed that more honey will be obtained by keeping the forces together as much as possible where the honey harvest is somewhat early and short, but where the harvest is late and long-continued a colony and its swarm may get more than the colony alone if it should not swarm. But bees don't always submit patiently to be kept from swarming, and some think it best to allow one swarm to each colony. Others say that by giving plenty of room both in the brood and surplus apartments there is little need of swarming.

Queen Going Into the Supers.

I have a colony of bees that hasn't swarmed this spring. Early in the spring I put two supers on, and as they did not swarm I investigated and found plenty of comb, but the queen had deposited it full of eggs. I would like to know the cause of her leaving the hive and going into the supers?
NEBR.

ANSWER.—Probably because of lack of room in the brood-chamber. If the supers contained sections, it was a little unusual, and might not happen again in a long time. If the supers contained extracting-combs, it was not strange for the queen to go up and lay. You can make sure against such a thing by using a queen-excluder under the supers, but such a thing is hardly needed under sections.

Swarms that Returned.

I have 20 colonies of Italian bees in Langstroth hives. Last week I had 15 swarms to issue, some settling and some not, but all returned to their hives—I did not save one. Why do they swarm and go back? I've only saved three swarms this season. Several colonies have swarmed as many as three different times, and have gone back. Why do they go back so much?
VIRGINIA.

ANSWER.—You say you've had a large number of swarms and have saved only three, the rest going back to their hives. Most bee-keepers would probably say that the swarms that went back to their hives were all saved, and saved in the best kind of a way.

Your bees have acted just as they would if the queens

were all elipt. When a queen's wings are elipt she cannot go with the swarm, so the swarm returns, sometimes not clustering at all, sometimes clustering before returning. The queen generally returns to the hive, if the hive is so placed that she can get back, and then the swarm may issue once or several times within the next week. After that time, or rather about eight days later than the issue of the first swarm, the young queen appears on the scene, and then the swarm is not likely to return.

If your queens were not elipt, it would seem that they were by some means incapable of flying with the swarm, a thing that would hardly seem likely to happen in such wholesale manner by accident. By the time this reaches you, you will probably have plenty of swarms that have not returned, and it would be interesting to have you report progress.

Another thing that just possibly might be, but hardly on so large a scale, is this: Your colonies might have intended swarming, then conditions being very unfavorable they may have given it up when the young queens were sealed over, and these swarms may have issued to accompany the young queens on their flight.

Questions on Transferring Bees.

1. How can I transfer bees from a box-hive to a dovetail hive?
2. When is the best time to do it?
3. How long will I have to leave the box-hive by the other one?
4. How late in the season can I wait and then have time for them to store honey enough to winter on? CONN.

ANSWERS.—1. There is nothing specially different in transferring into dovetailed hives from transferring into any frame hive. The instructions given in your text-book will be all right for dovetailed hives.

2. Fruit-bloom is generally considered the best time, altho it may be done at any time when honey is yielding.

3. After the contents of the box-hive are transferred there is no longer need to leave the old hive.

4. That depends altogether on the season and the honey-flow. If there is a heavy flow from fall flowers, it might be safe to transfer in August and have the colony all right for winter. Sometimes it would not be safe after the white clover harvest. On the whole, perhaps your better plan would be to wait till next season, and very likely you will be better satisfied to wait until the bees swarm, hiving the swarm in the frame hive, then taking out the contents of the box-hive three weeks later, when all worker-brood would be hatched out. Possibly, however, the bees may swarm yet this year, when you can hive the swarm in the new hive, setting the box-hive beside it, and 21 days later cutting out the contents of the box-hive, adding the bees to the swarm.

Yield of Basswood in Wet and Dry Seasons—Feeding Bees.

1. Will basswood yield as much honey in wet seasons as in dry ones? The basswood here is full of buds, but we have so very much rain all the spring. It is so wet every morning. It doesn't rain much in the daytime, only at night.

2. I have 42 colonies of bees, and have to feed them. There is very little white clover here this year, but plenty of young clover that came up this spring from the seed. The ground is full, but I think this will not yield any honey till next year, but the basswood is full of buds. I have fed two barrels of sugar already. Will it pay to feed bees in this way at such times? Would you feed them? IOWA.

ANSWERS.—1. Basswood may yield as much when very wet, but the nectar being thinner it takes more time to evaporate it, and consequently a less number of pounds in the sections.

2. It will probably pay to feed any time when bees are getting nothing and there is scarcity in the brood-chamber. It would be poor policy to let bees starve to death and give you no crop next year, when by an outlay of a dollar or so for each colony you might get back five times as much next year.

The Premiums offered on page 442 are well worth working for. Look at them.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

JULY 13, 1899.

NO. 28.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Pure-Food Commissioner for Illinois.—Mr. T. L. Chapman, of Jerseyville, an ex-State Senator, was appointed June 28th by Gov. Tanner as pure-food commissioner under the act past by the last general assembly creating the office. Referring to the appointment, Gov. Tanner had this to say, as reported in the Chicago Record:

"I consider this the most important appointment made or to be made by this administration. It is important from the fact that the law creating the office of pure-food commissioner is a very drastic one, giving to the commissioner extraordinarily arbitrary powers. Therefore, after worrying much over the selection, I arrived at the conclusion that it was the duty of the executive to select some one outside of the interests affected, wholly without prejudice—an honest, fair-minded man of good ability, broad-minded and conservative, yet firm. Taking this view of the matter I determined upon the selection of a lawyer, the best lawyer I could secure to take the place, a man who knew the law and had the courage to enforce it."

We certainly hope that Mr. Chapman is the right man for the place. If he proves so to be, he will find strong support among the bee-keepers of the State, who are anxious that he shall apply the law against the shameful adulteration of honey, particularly here in Chicago where the most of the adulterating is done.

Alfalfa, Grasshoppers, Bees: Their Relationship, is the title of a bulletin of the Department of Entomology of the

University of Kansas. The author is Prof. S. J. Hunter, a young man who made an excellent impression upon the national convention last year at Omaha. The pamphlet contains 152 octavo pages, and is a beautiful specimen of the typographical art, containing a large number of fine illustrations, mostly original. Eighty pages are devoted to bees, with some special attention to alfalfa as a honey-plant, and the advantage of bees to alfalfa. Alfalfa continues to secrete nectar as long as the blossom flourishes, and does its best under circumstances which tend to give the plant most vigorous growth. On dry upland the bees neglect it. Beginning with June it yields honey three or four months.

A careful comparison of two fields similarly situated except that only one of them had the visits of bees, showed 66 percent more seeds on the alfalfa visited by bees.

A plate gives six kinds of honey in test-tubes, showing the comparative degrees of light and shade. Alfalfa is a little darker than white clover. The lightest of all is a mixture of alfalfa and melon bloom. Sweet clover is the darkest of all except knotweed. Basswood, like alfalfa, is darker than white clover. In other States the comparison might be different.

Something like a condensed treatise on bee-keeping is given, the first part evidently being written by one who got his information at second hand, and not always from the most reliable source, as when it is said, "Should the colony be deprived of its queen, the workers hasten the appearance of a new queen by tearing down the partition walls between three surrounding cells, taking the contents away and leaving one egg to be fed for the throne." But these are minor blemishes.

Forty pages are occupied with plain and simple instructions for the beginner in bee-keeping, being written by a practical bee-keeper of experience, A. H. Duff. Mr. Duff writes as one evidently familiar with practical bee-keeping, and some of his ideas may be given at another time. Prof. Hunter has done a good work.

The Age of Brood-Combs that may be reached without unfitting them for good service is a matter in dispute. Some think they should not be more than five years old, while others think they should never be discarded on account of age. In *Apiculteur*, a foreign bee-paper, is reported a hive of combs that had been in constant use for 30 years, the combs being very dark, and bending easily without breaking. The bees reared in them showed no signs of deterioration.

The Honey Season for 1899 is thus commented upon by Editor Root in *Gleanings in Bee-Culture* for July 1:

So far reports are very meager, and such as have already come in do not indicate any very great show of surplus for most localities. There will be more of a crop than last year, but even then probably below the average. The season seems to be late everywhere, and basswoods are only just beginning to open in many places. So far reports seem to indicate that Colorado will more than hold her own. In California there will be a very light crop—less than a quarter. We have received letters from Wisconsin, Iowa, and Tennessee, indicating no honey; but for Wisconsin, at least, it is a little early to forecast the crop. In New York, reports indicate that there will be a fair crop of clover and basswood, which will, no doubt, be followed by the usual flow from buckwheat. From Michigan we have some bad reports as well as good ones. N. E. Doane writes that willow-herb has "about had its run," and this is usually one of the unfailing sources of honey. Byron Walker, of Michigan, writes much more encouragingly. The nectar-flow in and about Medina, while better than last year, will be rather light. Mr. Burt will get a super of comb honey from each one of his 300 colonies.

The conditions in the latter part of May and early part of June, while very favorable, have been rather unfavor-

able during the last two weeks of June. We have had quite hot weather followed by too many cool days and nights, and there is not liable to be a nectar secretion in cool weather; altho this morning (June 30) when the temperature was as low as 55 degrees, by a tested thermometer, the bees were working lively on the basswoods in front of my house. At this writing, bees are gathering honey from both clover and basswood, and if they only *hang on* we shall have nothing to complain of.

Curious Result from Scraping Hives.—We take the following paragraphs from the British Bee Journal:

A neighbor of mine came to me about 12 months ago with his face swollen so that he could hardly see, and ask me what I thought was the matter with him. "I should say you have been stung," I replied. He assured me he had not, but that he had been scraping out and cleaning two bar-framed hives he had had given him, and thought the dust from the hives had caused the swelling and rash. However, he got better of that, but now, a week or two ago, when he was cleaning out his shed (where he had a year ago scraped the hives), he says he must have got some more of the dust into his face and arms again. But he has been much worse than before, for he has been treated by a doctor for a week. He never touched the hives on the second occasion. Is this not very curious?—F. W. MOREY.

[It is so "curious" that we cannot possibly imagine your friend being right in attributing the trouble to the bee-hives.—EDITORS.]

Probably most bee-keepers will have the same opinion as the editors. It is just possible, however, that the dust of the propolis may have occasioned the trouble. Two or more cases have been reported on this side the water, in which a similar swelling followed the act of scraping sections, and there may be cases in which the skin is abnormally sensitive to the irritation of propolis.

Transferring Bees—Three Methods.—Mr. F. G. Herman, of New Jersey, gives the following three ways for transferring bees, in a recent issue of the American Agriculturist:

There are at least three ways of transferring bees from box-hives into movable-frame hives. The old method is to pry open the old hive with cold-chisel and hammer and cut out the combs and fit them into the frames of the movable-frame hive, and fasten them in with sticks and strings. After trying this method on several colonies I must pronounce it messy, sticky and unsatisfactory. A much better way is to drive them out by the following plan:

Take the hive of the colony which is to be transferred under a tree in the shade, or alongside of a building, and turn it bottom up, place on top of it an empty box of the same size, blow in a little smoke at the bottom occasionally, and drum on the old hive with a couple of sticks for 10 or 15 minutes. Nearly all the bees and the queen will go up into the empty box above. In the meantime place the hive in which you wish to put the bees on the stand where the old hive stood, so as the field-bees which will be coming in all the time have a place to go. Of course they will be rushing in and out, not knowing what to make of it. Take the box of bees and dump them in front of the new hive, and they will soon run in and make themselves at home. Stand the old hive in a new location, and drum out again in 21 days. Put these bees into a new hive, or add them to the old colony, as you prefer. If one desires two colonies from the one, it is best to let the old box-hive colony cast a swarm first, then drum in 21 days, and the one drumming will be all that is necessary.

Still another way, which is better and less work than either of the above methods if one wishes to keep the whole force together and get the most honey, is to take a movable-frame hive full of combs or foundation a week or two before swarming-time, and place under the box-hive, closing the entrance of the upper hive, and compelling the bees to go thru the new one. When honey begins to come in rapidly the bees will crowd the queen into the lower story, always putting the honey above the brood. When the queen is laying nicely in the lower story, put a queen-excluder between the two hives, and soon all the brood will be hatched out above, and the combs will be filled with honey. It can then be taken off, the combs cut out, the honey extracted, the old combs melted into beeswax, and the old hive cut up

into kindling-wood. I am trying some this way now, and find it the most satisfactory method of all, getting more honey and wax, and keeping down the increase.

The Philadelphia Convention of the United States Bee-Keepers' Association, as has been announced before, will be held Sept. 5, 6 and 7, 1899. Dr. A. B. Mason, the Secretary, sends the following information as to railroad rates, lodging, etc., which we are pleased to give a place in these columns:

STA. B. TOLEDO, OHIO, June 26, 1899.

MR. EDITOR:—I have been faithfully trying to get the railroad rates to the G. A. R. encampment at Philadelphia for the information of those bee-keepers who may wish to attend the convention of the United States Bee-Keepers' Association on the 5th, 6th and 7th of next September, and find that in the territory covered by the Central Passenger Association the rate will be one cent per mile each way, "with a minimum of \$11 (except that the fare will not apply via Pittsburg, Pennsylvania road and Washington), but via Harrisburg direct," but the \$11 rate will be waived where the current first-class one-way fare is less. In such cases the fare will be one cent per mile each way in the Central Passenger Association territory added to the authorized one-way fare for the round-trip from the nearest Trunk Line gateway (or station). Tickets for sale Sept. 1 to 4, inclusive.

The rate in the territory covered by the Trunk Line Association will be "one fare for the round trip with a minimum of \$1.00, except that the fare from New York and Baltimore will be \$3.00; from Washington \$4.00; from Newark, N. J., \$2.85; from Elizabeth, N. J., \$2.75; and proportionately from intermediate points. One fare to New York plus \$3.00 from points west of Binghamton and Syracuse via New York, going and returning same route." Tickets to be sold, and good going, Sept. 2 to 5, inclusive.

The Central Passenger Association territory includes that part of Canada lying south of a line running from Toronto nearly west to Lake Huron; the southern peninsula of Michigan, that part of Illinois lying east of a line running from East St. Louis to Chicago, including both of these cities; all of Indiana and Ohio; that portion of Pennsylvania lying west of the Allegheny River, and that part of New York lying west of a line from Salamanca to Buffalo.

The remainder of the United States lying east of the Mississippi River, and south of the Ohio River, and those portions of Pennsylvania and New York not in the Central Passenger territory above described, and all of New England, are in the Trunk Line Association territory.

In both the territories named above, "tickets will be good returning to Sept. 12, inclusive; except that by deposit of ticket with joint agent at Philadelphia, between Sept. 5 and 9, both dates inclusive, and on payment of a fee of 50 cents, return limit may be extended to Sept. 30, inclusive."

Rates have not yet been fixed by the Southwestern Passenger Bureau, and the Western Passenger Association, but both have promised to inform me as soon as announcement is made."

By inquiring of the station agent any one can readily learn the rate of fare.

Side trips to Washington, Richmond, Norfolk, Gettysburg, Antietam and other points of interest will be provided for at about one fare for the round trip, or a cent and a half per mile for circuitous routes.

In a letter just received from Mr. F. Hahman, secretary of the Philadelphia Bee-Keepers' Association, he writes in substance:

"If those expecting to attend the convention will write me we will find quarters for them; those not notifying us will have to take their chances, as we cannot engage rooms for anybody except those we are sure will come."

Let me suggest that all such as desire entertainment write Mr. Hahman *at once*, or as soon as they have decided to attend the convention, so as to be sure and *reach him* by Aug. 15 or 20, and tell him what you wish provided. Mr. Hahman's address is Harrowgate Lane, Sta. F., Philadelphia, Pa.

The Philadelphia Association proposes to find good lodging-places for all who notify Mr. Hahman, and breakfast at the lodging-places if possible; and dinner and supper can be had at some of the numerous restaurants near the place of holding the convention, which will be in Franklin Institute, at 15 South 7th Street, between Market and Chestnut Streets.

A. B. MASON, Secretary.

Why Not Just Double

The List of Subscribers to the Old American Bee Journal?

We really believe that if ALL the present readers of the American Bee Journal were so inclined, they could help to double its regular list of subscribers before August 1, 1899— or during the next 5 or 6 weeks. We do not find any fault with what our subscribers have done in the past toward increasing the list of Bee Journal readers—for they have done nobly—but why couldn't the doubling of the list be accomplished within the next month? We surely think it could be done, and in order that it may be easier for those who help in it, we will make a **SPECIAL NEW SUBSCRIPTION OFFER**, and also pay all who will aid in securing new subscribers. Here is the offer:

Six Months for 40 Cents to a New Subscriber...

Yes, we will send the American Bee Journal **EVERY WEEK** from July 1, 1899, to Jan. 1, 1900—26 numbers for only 40 cents, to a **NEW** subscriber. In addition to this we will send to the present regular subscribers, for the work of getting new 6-months' readers, their choice of the premiums mentioned below, but no premium will also be given to any new subscriber on these offers, under any circumstance:

For Sending 1 New 40-cent Subscriber
 —Your choice of one of the following list:

- Poultry for Market.
- Our Poultry Doctor.
- Capons and Caponizing.
- Foul Brood—Kohnke and Cheshire.
- 10 copies York's Honey Almanac.

For Sending 2 New 40-cent Subscribers
 —Your choice of one of the following list:

- Dr. Howard on Foul Brood.
- Monette Queen-Clipping Device.
- Bienen-Kultur (German) by T. G. Newman.
- Dr. Tinker's Bee-Keeping for Profit.
- Pierce's Winter Problem in Bee-Keeping.
- Bees and Honey (160 pages, paper) by Newman.
- 20 copies York's Honey Almanac.

For Sending 3 New 40-cent Subscribers
 —Your choice of one of the following list:

- Bees and Honey (160 pages, cloth) by Newman.
- Bee-Keeping for Beginners, by Dr. J. P. H. Brown.
- Bienenzucht und Honiggewinnung (German) by J. F. Eggers.
- Advanced Bee-Culture, by W. Z. Hutchinson.
- 30 copies York's Honey Almanac.

For Sending 5 New 40-cent Subscribers
 —Doolittle's Scientific Queen-Rearing.

For Sending 6 New 40-cent Subscribers
 —Prof. Cook's Bee-Keeper's Guide.

NOW FOR A GRAND PUSH FOR NEW SUBSCRIBERS!

It seems to us that with the above low rate to new subscribers, and also the premiums offered, we should get such a landslide of new subscriptions as will make us sweat to care for them during the next few weeks without any help from the hot weather. **WE** are ready now to enter the new names and mail the premiums. Are **YOU** ready to go out and get them, and then send them in?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Amount of Drone-Comb in a Large vs. a Small Brood-Chamber.

Query 96.—Will there be more drone-comb when a very large brood-chamber is used than in a small one? My experience says there will be more, after one season's trial.—ILLINOIS.

- A. F. Brown—Yes.
- E. Whitecomb—Yes.
- Dr. A. B. Mason—Yes.
- O. O. Poppleton—I think so.
- Mrs. A. J. Barber—I think so.
- Prof. A. J. Cook—I do not think so. It

A RARE CHANCE

to purchase an apiary of 200 colonies of Italian and Carniolan Bees in 10-frame Langstroth and Dovetailed hives. The hives are two-story with 10 brood and 8 extracting-frames in top story, all wired for extracting. Combs are straight and in fine condition; last year's crop of honey was over 700 gallons from 150 colonies.

Purchaser can occupy the present good and convenient location of two acres, well shaded, with a comfortable residence for a family, for \$10.00 per month, within 100 yards of fast line of electric cars that go thru main part of New Orleans every 5 minutes. Mail service twice a day. Poultry-houses and yards at cost of wire-netting in fences, and some fine poultry for sale; also furniture in house.

All must be sold, and location abandoned on account of poor health. All honey, poultry and eggs can be sold in city home market at good prices. Correspondence solicited.

Queens Untested Italian, 50c each; Tested, \$1.00 each. Queens large, yellow, and prolific. Address, **E. W. HAAG, Canton, Ohio.** (Successor to THEODORE BENDER.)

Root's Column

GLEANINGS AT REDUCED RATES....

We do not need to tell you about our journal, for it will speak for itself; but as an extra inducement we make the following low offers:

Offer No. A.

For 25 cents we will send GLEANINGS IN BEE-CULTURE from the time your subscription is received until January, 1900. If you send in your order promptly you will get 6 months for only 25 cents.

Offer No. B.

For \$1.00 we will send an untested Italian Queen worth 75 cts. and GLEANINGS IN BEE-CULTURE one year.

Offer No. C.

For \$1.00 we will send GLEANINGS IN BEE-CULTURE the rest of this year and all of next year, that is, from the time your subscription is received until January, 1901. The sooner you take advantage of this offer, the more numbers you will receive.

Offer No. D.

For 50 cents we will send GLEANINGS IN BEE-CULTURE 6 months beginning July 1 and Vol. I of Gleanings. This is for the year 1873. There are many interesting things. There are 12 articles on "Starting an Apiary," and while some of these may not be practical now, there is much valuable information and it gives a good idea of bee-keeping at that time. Our supply is limited and of course we cannot continue this offer long.

Old as well as new subscribers may take advantage of these offers, but all arrearages on back subscriptions must first be paid at \$1.00 per year.

ADDRESS

THE A. I. ROOT CO.
MEDINA, OHIO.

depends upon the proportion of bees to the space, and general thrift.

W. G. Larrabee—I don't know.

R. C. Aikin—Yes, on an average.

C. H. Dibern—Perhaps, but I see no good reason for it.

Mrs. L. Harrison—I never experimented along that line.

Dr. C. C. Miller—Generally, yes. Properly managed, no.

J. A. Green—I think there will be a little tendency that way.

J. A. Stone—No more in proportion to the size of the hive.

E. France—I guess there would, but I would use the big hive.

Dr. J. P. H. Brown—Yes, in the majority of cases there will be more.

Emerson T. Abbott—Yes; this is a self-evident fact, it seems to me.

Rev. M. Mabin—In the brood-chamber, yes; and I judge in the super, also.

Mrs. J. M. Null—Yes, as a rule; but with young queens but little drone-comb is built.

Eugene Secor—I have not observed anything corresponding with your experience.

R. L. Taylor—Yes, from the nature of things, not only more, but more in proportion.

P. H. Elwood—You are right—more worker-comb, too. But more drone, relatively.

J. M. Hambaugh—I think not. Use full sheets of worker foundation, and obviate this difficulty.

G. M. Doolittle—No, if you fill the frames with comb foundation of worker size. Yes, if you use only starters in the frames.

J. E. Pond—I think the experience of the "querist" will be found to be that of nearly all the apiarists in the country.

C. Daveport—My experience has been that there will, as a rule, but it largely depends upon conditions. I have had colonies build about half drone-comb in 8-frame hives.

Adrian Getaz—If both colonies are of the same size there will be more drone comb in the larger brood chamber. The larger the colony is in proportion to the brood-nest, the less drone-comb will be built.

D. W. Heise—Yes, if the colony is given the whole brood chamber when hived, without full sheets of foundation, honey coming in freely, and the queen should happen not to be a very prolific one.

Chas. Dadant & Son—If there is more, take it out. The quantity of drone-comb built depends on the prolificness of the queen at the time when comb is built. A prolific queen will obtain a greater quantity of worker-comb.

E. S. Lovesy—My experience is that this question is governed more by the habits of the bees than by the size of the hive. When I find a colony exhibiting a penchant for building drone comb, I aim to keep it from being in or near the brood-nest, and if I find unnecessary drone-brood I remove it from the hive.

G. W. Demaree—In the brood-"nest" proper, the age of the mother of the colony has more than any other factor to do with the amount of drone-comb built by the bees. Hive two swarms on half-inch starters, let the one colony have a young queen, and the other a very old queen; now watch the results, and your question will be answered without regard to size of hive.

Queens! Queens!

If you want good queens, try mine. They are strictly pure Italians, and are all purely Italian. My strain of Italians are unequalled as honey-gatherers, and have no superior. Untested Queens, 75 cents each; Tested, \$1.00; Select Tested, \$1.50.

Bees by the Pound

YOUR OPPORTUNITY!

We have arranged with a large bee-keeper in Cedar County, Iowa, to furnish ONE-FRAME NUCLEI OF BEES WITH WARRANTED PURE ITALIAN QUEEN and ONE POUND OF PURE ITALIAN BEES—all for only \$2.00; or in lots of five at \$1.80 each. There are only 75 for sale. Better order quick if you want any. If more of the queens are wanted, these can be had at 75 cents. All queens reared by the Double process.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

Bees Doing Fairly Well.

My bees are storing linden honey and have been for one week. They are progressing tolerably well with their work, having sealed some honey. They could have done more if the weather had been warm instead of cool. The sourwood furnish bloom for two weeks before the linden came, but the bees stored only a limited quantity of honey from the sourwood. There is a good supply of linden bloom, which will be over by July 15. I am somewhat hopeful for a summer harvest.

JOHN M. RYAN.

Marshall Co., Ala., June 27.

Extracting Clover and Basswood.

My bees have stored quite a reasonable amount of clover and basswood honey. I am extracting it now, and have been for two weeks. The white honey-flow is now closing. At this date last season the bees did not have, in the whole hive, five pounds of honey; now the hives are full of honey.

D. A. CADWALLADER.

Randolph Co., Ill., June 25.

Ants in Texas.

On page 386, Prof. Cook gives some very interesting points about ants. He speaks of the agricultural ant of Texas clearing the ground, sowing and reaping. Now, I believe he is mistaken, or misinformed, for I have been all over Texas, and if there was such a thing I surely would have heard of it. It is true, there is a large red ant—perhaps the kind he has reference to—that col-

lects grains of wheat, nats, etc., also mounds about their entrances. We are bothered here in parts of Texas very badly with small red ants; they get into the hives, bore holes in the cappings of the brood, and kill it. We lost several colonies this way while in Lampasas county. We also lost several fine queens, by leaving them where the ants could get to them. They seemed to sting the queens, but didn't bother the workers. Even here, where there are hardly any ants, we have to be careful about our queens, the ants seeming to bother them more than anything else about the bees.

H. H. HYDE.

Williamson Co., Texas, June 25.

Very Little Swarming.

Here it is the last of June and I have not had a swarm from my 80 colonies, and but very little honey as yet. There have not been 50 swarms out of over 3,000 colonies in Otero county, and the loss was from 10 to 70 percent last winter.

F. W. CHUR.

Otero Co., Colo., June 27.

Good Prospect for Fall Honey.

The white clover was winter-killed here and our bees have to be fed yet. The prospect for fall honey is good, as so far we have had lots of rain.

CHAS. BLACKBURN.

Buchanan Co., Iowa, July 1.

Good Weather Needed.

Basswood, buckbush, and white sweet clover began blooming the first of this week, and the bees are very busy, and in good shape to store honey, if the weather man will give us better weather than we have had for the past two months.

W. S. YEATON.

Woodbury Co., Iowa, June 30.

Doing Well on Clover and Basswood

Bees are doing well on clover and basswood. If we only had lots of strong colonies I think we would get some honey, as they have been doing well the last few days.

ARTHUR STANLEY.

Lee Co., Ill., June 29.

Not a Prosperous Season.

Last winter was a very severe one here, and was hard on the bees. Some bee-keepers lost all. I lost about 20 or 30 colonies out of 100. So far they do not seem to be doing much. I do not look for a very prosperous sea-on for honey.

WM. AIKEN.

Ontario, Canada, June 28.

Bee-Hunting—Information Wanted.

I am seeking information on the line of hunting wild bees. Mine having joined the majority in this section the past winter, I would like to find some wild ones to stock up with again, as those that have any left hold them "out o'sight" as regards price.

There are some wild ones here now in the timber, for I found a colony about two weeks ago, and more are going to the woods, as I have heard of two colonies that were seen to go already. At this season of the year they will not work on honey scarcely at all, and it is impossible to get any lines that way. If a bee is caught in a box she will probably fill up on the honey, and when you let her go she whirls around so much that one loses sight of her, and she fails to return at all, or, if she does, it is to buzz around a little and then go into the flowers.

Is there a bait on which bees will work when flowers are plenty? If any one knows of any he will confer a favor by making it known. I would like a plan for finding bees in June, July and August.

Among the readers of the American Bee Journal there must be many bee-hunters that can give the best method for hunting at this season of the year. To look over all the timber here would be impossible. There

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of **Bee-Keepers' Supplies,**

They have also one of the **LARGEST FACTORIES** and the latest and most improved machinery for the manufacture of **Bee-Hives, Sections, &c.**, that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the **BEST GOODS AT THE LOWEST PRICES.**

WALTER S. POWDER,

512 Mass. Ave., INDIANAPOLIS, INDIANA.

are some tame bees scattered all thru the country. I have tried the "stink bait" of corncobs and wine, but that is not satisfactory, as some of the time they will not touch it at all. I would like to find them as soon as possible, so that I can save the bees to stock up my apiary again. I have been quite successful in hunting bees in the fall after frost, but at this season of the year it is quite different, so I come to the readers of the American Bee Journal to help me out. L. J. CLARK.

Winona Co., Minn.

[If any of our readers can help Mr. Clark, we would be pleased to publish it.—ED.]

Floods in Texas—Much Damage.

We have had, I think, at least 18 to 24 inches of rainfall since Tuesday, June 27. Wagon-roads are entirely impassable for vehicles; railroads, culverts and fills are washed out, and the roadbed entirely gone in many places in the creek and river bottoms. I had 60 odd nuclei 15 miles from here on the river bottom; I am satisfied that they are gone, but I can't get there nor hear from there. I have had no mail for two days; trains can't possibly get over the road before Sunday. It still looks like more rain—nothing to equal this in 32 years, so the oldest settlers say. Some think the creeks and rivers are higher now than then. E. R. JONES.

Milam Co., Tex. June 30.

July 4, 2 p.m.—No trains since June 25th. It is reported that the trains will get thru this afternoon. The Brazos River is higher than the oldest settlers ever saw it. Reports say that the town of Calvert is in the water, and Hearne is just out of water, the break-water from the two rivers (Big and Little Brazos) meeting just outside of town. Undoubtedly many lives are lost, but we can only guess yet to what extent. Vehicles, farming implements, stock and household goods of all kinds have been coming down Little River and the Brazos for four or five days. Farms in the bottoms are all the way from 4 to 15 feet under water now, and have been for four days. E. R. J.

P. S.—See our convention notice below.

Convention Notice.

Texas.—The Central Texas Bee-keepers' Association will meet July 20 and 21, 1899, at Milano, Texas. On account of this meeting I have received a rate of one and one-third fares for the round trip on the certificate plan from all points in Texas, on the lines of the following railroads: G. C. & S. P.; I. & G. N.; H. & T. C.; M. K. & T.; Ft. W. & R. G.; the Southern Pacific, and the Cotton Belt. Don't forget to tell the ticket agent where you are going, and take his receipt showing that you have paid full fare to Milano. If you cannot get a thru ticket to Milano, take a receipt wherever you buy a ticket, showing that you have paid full fare. A cordial invitation is extended to all bee-keepers. Remember there will be no hotel bills to pay. E. R. JONES, Com. on Program.

BEES FOR SALE I will sell to make room, 200 COLONIES OF BEES in my non-swarming migratory hives. Address, 28A21 JAS. H. DAVIS, Marksville, La.

EVERY BEE-KEEPER WILL APPRECIATE THIS.

A MOST WONDERFUL OPPORTUNITY

The Bee-Keeper's Guide

Or, Manual of the Apiary,
—BY—
PROF. A. J. COOK.

460 Pages—16th 1899 Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

QUEENS

Either 5-banded, Golden or from IMPORTED Italian mothers, 60c each; or 6 for \$3.00. A few fine breeders at \$1.50 each. Give me a trial and let me surprise you. Satisfaction or no pay.
CH. H. THIES, Steeleville, Ill.

26Atf Please mention the American Bee Journal.

Golden Italian Queens!

5-banded Untested, 60 cts. each; Tested, \$1.00 each.
1-frame Nucleus, \$1.50
2-frame Nucleus, 2.00
3-frame Nucleus, 2.50 each, with untested Queen.

I am running 800 nuclei, and can send Queens by RETURN MAIL. I have no 3-banded queens, and no 3-banded drones in my apiary. Am making a specialty of rearing the 5-banded strain this season. My 5-banders are working on red clover. Queens are reared by Doofittle's method. I insure safe arrival of queens. This is a post-office money order office. Address your orders to

Dan'l Wurth, Falmouth, Rush Co. Ind.
and receive fair treatment and prompt service. If you want 5-banded queens that are reared in a yard where there are no 3-banders, I am at your service. Parties wanting more than one queen will do well by writing for prices.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 8.—Not any of the new comb from other than the Southern States has appeared on our market; most of that is amber to dark, and hence sells at an average of 8@10c. New white that would grade choice to fancy would sell at 13c; off grades of white, 11@12c. Extracted, white, 7@7½c; ambers, 6@7c. Beeswax, 20@27.
R. A. BURNETT & Co.

KANSAS CITY, July 7.—A small shipment of new comb honey on the market is selling at 14@15c. Good demand. C. C. CLEMONS & Co.

NEW YORK, June 9.—Demand good for extracted honey, all kinds, and same finds ready sale at the following prices: Fancy, 7@7½c; choice, 6@6½c; fair, 5½@6c; common, 5@5½c per gallon. Some demand for comb honey at from 11@12c for white, and 9@10c for amber. No more demand for dark. Beeswax dull at from 25@27c per pound, according to quality.
HILDRETH & SEGELKEN.

SAN FRANCISCO, June 21.—White comb, 10@10½c; amber, 7½@9c. Extracted, white, 7½@7½c; light amber, 6½@7c. Beeswax, 20½@27c.

Values for new crop comb and extracted are ruling much the same as lately current for old, but demand is not active at full figures, large dealers deeming these prices too high for round lots.

CLEVELAND, March 9.—Fancy white, 13@14c; No. 1 white, 12@13c; A No. 1 amber, 10@11c; No. 2 amber, 9@10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.
A. B. WILLIAMS & Co.

BOSTON, May 17.—Fancy white, 12½@13c; A No. 1, 11@12c; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7½@8c; light amber, 6½@7c. Beeswax, 27@28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is liked at this season of the year.
BLAKE, SCOTT & LEE.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11@12c; some very poor selling at 6@7c, and dull. No more business in honey before the opening of the ensuing season.
BATTERSON & Co.

OMAHA, June 2.—A few little lots of new honey from Texas have made their appearance on the market. The stock was put up by inexperienced people and only sold at moderate prices. Extracted of fairly good flavor brought 5½@6c. Comb honey put up in 6-gallon cans and filled with extracted sold at 6½c. This is a most undesirable way of packing comb honey. Trade does not care for it.
PEYCKE BROS.

DETROIT, April 10.—Fancy white, 12c; No. 1, 10@11c; dark and amber, 8@9c. Extracted in fair demand without change in price. Beeswax, 25@26½.

Decreasing demand and the attempt to crowd sales have forced down prices on comb honey.
M. H. HUNT.

THIS

Wood Binder

will hold one year's numbers of the AMERICAN BEE JOURNAL and will be sent by mail for **20 cents.** Full directions accompany each Binder. The issues of the JOURNAL can be inserted as soon as they are read, and preserved for reference in book form.

By paying for a year's subscription STRICTLY IN ADVANCE this Binder will be sent, postpaid, for 10 cents extra.

BIOGRAPHICAL

Miss Pickard and Her Apiary.

Miss Ada L. Pickard, who is shown herewith in her apiary, resides in Richland Co., Wis., and is one of the few lady bee-keepers who is making a wonderful success in her chosen field. We are glad to be permitted to place before our readers not only the picture, but also the following few words from Miss Pickard about herself and her work with the bees:

When I was a small girl my mother purchased Mr. S. J. Freeborn's apiary, numbering 100 colonies, which he placed upon our farm in Richland County during the summer of 1887. She being very much interested in the work succeeded in interesting me during the vacations. I always worked with her until the spring of 1898, when we moved 100 colonies about 12 miles from home, and I took charge of the apiary having sole management of it, and securing, as the result of my labors, 16,000 pounds of fine basswood honey. The picture represents me in my apiary last summer.

When fall came, we removed our bees home and placed them in winter quarters. Having excellent success in wintering, we moved 111 colonies to the

place where I now am, and we are awaiting the results. The prospects are very good for a crop of honey this year, as the basswood trees are hanging loaded with bloom.

We trust that this short account may prove an inspiration to other daughters of our readers. They may not be able to "go and do likewise" to the extent which Miss Pickard has attained, but in all probability they might be very successful in their efforts along the bee-keeping line.

We regret that Miss Pickard didn't go a little more into the details regarding herself and her work, but as we hinted when writing her that she need not give any clue to her age, we presume she felt excused from giving many other interesting particulars as well.

In the last report issued by the Wisconsin Farmers' Institutes, we find the following from Miss Pickard's pen, being a portion of an entertaining contribution, entitled, "The Importance and Development of Bee-Culture:—"

THE BEE-MASTER, PROGRESS IN BEE-KEEPING, ETC.

To be a thoro bee-master requires as much intelligence, forethought, and skill, as to be a good lawyer, physician, or any other professional, and withal a clear perception of the relation of cause and effect. Some people are inclined to think that bee-keeping is a pleasant pastime which lazy and incompetent people can take up with success, thinking all that is required is to put bees into a hive in some out-of-the-way place, and that they will "work for nothing and board themselves." And so they may, but if the owner desires to obtain any surplus for his own table, or for the market, he must give them further care, and unless

Miss Ada L. Pickard and Apiary—Richland Co., Wisconsin.

he has a heart for the work, so that he finds some degree of pleasure in caring for them, he had better not attempt to keep them at all, as they will only prove a source of annoyance without profit.

To make a successful bee-keeper requires a special gift, or a natural aptness for the business, the faculty of perceiving what needs to be done, and an inclination to do it promptly. The old Spanish adage, "Never to do anything to-day which can be put off until to-morrow," does not apply to bee-keeping, as it savors too much of slothfulness; but the old Anglo-Saxon maxim, "Never leave until to-morrow what can well be done to-day," will be found more applicable, being much more in harmony with the assiduous activity of the bees.

We are living in a progressive age. No other period in the world's history has ever been signalized by such wonderful developments in science and art as has been brought to light this 19th century. The great labyrinth of Nature's mysteries has seemed to be set open unto men, and forces and principles which have lain dormant since the beginning of the creation, have in our day been brought forth and made subservient to the will of man with astonishing results. And while such unparalleled progress has been made in other directions, bee-keeping has also received its share of attention, and I feel quite safe in saying that more progress has been made in the management of bees, during the latter part of this century, than during all the thousands of years of previous history.

Bee-keeping in its present stage of development is fully entitled to take rank as one of the arts, and were it not for the variability of the seasons, the changeableness of the weather, and other atmospheric conditions upon which the secretion of nectar in the flowers is so largely dependent, and upon which hinges the turning-point of success or failure, all of which are entirely beyond our control—I say, were it not for these uncertainties, then bee-keeping might properly be classed as a science; but inasmuch as the variation of seasons necessitates a variation in management of the bees, therefore no set rules can be established which will work satisfactorily under all circumstances that may arise; but the judgment and skill of the apiarist needs to be constantly exercised in order to discover just what needs to be done, and when and how to do it.

Altho the manipulations of an apiary are widely different from farm work, as the practice of medicine is different from the practice of law, yet a few bees in the neighborhood are a real benefit to every farmer or fruit-grower, because the bees evidently perform a very important part in the fertilization of the blossoms of fruit and seed bearing trees and plants. Therefore, let the farmer, fruit-grower, and bee-keeper, live in harmony and good-will, for that which promotes the interest of one, promotes the interest of all. Give the bees a chance. ADA L. PICKARD.

Dead Brood—Kingbirds—Honey-Dew.

BY PROF. A. J. COOK.

IT will be remembered that in 1894 there was much complaint of dead brood in the apiaries of Southern California. The present season shows the same condition again. I have received samples from nearly every section of Southern California within the past few weeks, always attended with the inquiry, "Is it foul brood?"

This dead brood is not at all like foul brood, and any one who attends to the following description carefully, will have no difficulty in distinguishing the one from the other: In this case, the characteristic, most disagreeable, odor of foul brood is wholly wanting; the sunken cell-cap, with its frequent perforation, is also absent. The dead brood is always in the form of larva, and never in the sticky, pasty, unctuous mass so characteristic of foul brood. We insert a pin and draw a decaying larva from the cell, and it is not a stringy orropy substance which springs back when it lets go the pinhead, as is true of foul brood, on the whole, yet it often appears coffee-colored or a rich, dark brown, as does

foul brood. The surest way to tell is in the character of the decaying substance in the cell. If the larva is always found, showing the form even in its decay, instead of the stringy, elastic, pasty mass, then it is not foul brood.

I had a good deal of this in my hives in 1894, but I found it only in colonies in a starving condition, and as soon as I fed the bees properly the trouble disappeared. I have recently examined several colonies, where there is abundance of honey and pollen in the hive, and I found no sign of the disease. I believe it comes from some condition which kills the larva. I have pretty good reason to think that this is usually lack of stores. If it is sometimes present with abundance of food, as is reported by some of our good authorities, then it must be some other cause that brings death to the brood. Once dead, natural decay commences. The number of dead bees is not usually sufficient to produce any serious stench about the hive.

I suggest to all who are disturbed with this dead brood, to feed the bees, or see that they have plenty of honey, and I predict that their experience will be like mine in 1894—the trouble will disappear.

It is significant that we hear nothing of this trouble in good seasons, and, so far as I have observed, see it only in apiaries where stores are very short in the hives. Nearly all who have sent me this dead brood this year, have stated that the bees are very short of honey.

THE KINGBIRDS.

There are two birds in the United States that kill bees, both workers and drones, and I feel sure that they would not hesitate to take the finest queen should opportunity offer. The birds are wholly insectivorous. They belong to the family Tyrannidae, which also includes the common, well-known pewee. Both, or possibly all three, species belong to the genus Tyrannus. They are all known as kingbirds, bee-martins, or tyrant fly-catchers. The Eastern one is Tyrannus tyrannus, while the one here in Southern California is Tyrannus verticalis. Another species I have taken here is T. vociferans. The Eastern one is dark ash, almost black, while the California species are ashy with yellow bellies. All have a characteristic red patch on the crown of the head.

I was interested in the account in the last American Bee Journal of these birds. We have found them here right at the apiary, and I have seen them dart down to the hives. They were taken, their stomachs examined, and no bees found, but, instead, the robber-flies, which are among the worst bee-enemies we have. So about here, I feel confident that they are more friends than enemies, even of the bees. Yet I know from actual examination that the Eastern kingbird does upon occasion take bees, and workers at that. I presume the California species may rarely do the same thing, but none of those killed here have shown any bees in the stomach. Robber-flies, cut-worms, grubs and locusts have been found abundantly in their stomachs. Even granting that they do levy occasionally on the apiary, they take without doubt a score of harmful insects to one bee.

I should like to know how they manage the stings when they kill worker-bees. If they swallow the bees instantly, they must be stung, as the bee is too quick with its defense-organ to permit escape. I have taken five stings from the throat of a toad that had taken five worker-bees just before. We can believe a tough, non-sensitive toad might wink at such misfortune, but the more sensitive kingbird, we should think, would wince, and feel the pain acutely. Can it be possible that they have some way of avoiding the sting? I hope any who have opportunity will observe on this point. I should like to receive stomach and head and throat of a kingbird that had been really taken after eating worker-bees.

HONEY-DEW—ITS ORIGIN.

I am surprised at Mr. McKnight's article critique in the Bee-Keepers' Review, of my position regarding honey-dew. I did not suppose I needed to prove that honey-dew was generally from plant-lice (aphides) or scale (not scab) insects (coccids). We have only to observe to see the exudation and fall of the nectar from the insects. Whatever may be the ultimate truth, this is certainly true: Nearly all such honey-dew is from insects, as any one will see upon superficial examination. Very little, if any, is secreted by the plants, and none at all falls from the sky. Mr. M.'s suggestion that the plant forms the honey-dew, and the insects (plant lice and scale insects) sip it up, can be refuted by a very little close observation. We see the nectar coming from these insects, but we never see them sipping it up,

for the very good reason that they do not do it, no more than do bees pierce sound fruit.

I wish any one who finds what they think is plant-secreted honey-dew would send me a sample of the plant with the honey-dew on it. Claremont, Calif., June 4.

Are Italian Bees Yellow or Maroon?

BY DR. C. C. MILLER.

A "STRAY STRAW" in Gleanings in Bee-Culture for July 1, reads as follows:

"G. M. Doolittle says, in American Bee Journal, 'I never saw a single worker-bee from an imported queen that had any yellow on it at all. The color was always a maroon, chestnut, or leather color, not yellow.' My imported queens, or those that I bought for imported, have always had workers that I called yellow. Now the question is, Have I been swindled, or has some one been working off maroon bees instead of yellow on Doolittle? I don't believe I ever saw a dozen imported Italian queens, and I doubt whether Doolittle has seen many more than I, for I've been buying since he thought no more importations were needed, and at Medina you've had perhaps more imported queens than at any other place. Please tell us, are the workers of an imported Italian queen yellow or maroon?"

Editor Root, in his foot-note to the above "Straw," says this:

"I do not know where Mr. Doolittle gets his notion of colors; but if he will consult his good wife I feel sure he will have to revise his idea somewhat. I do not think I am boasting when I say that I have seen perhaps 50 imported queens where Doolittle or yourself have seen one; for we import from 50 to 75 every year. Years ago, as you say, Doolittle went on record as saying that he believed further importation was unnecessary, so I take it he has not seen an imported queen for some time. The color-bands, both on bees and queens, are what are generally called 'leather' color. I never saw one queen or bee direct from Italy that had bands that were either chestnut or maroon. Maroon? my, oh my! what's the matter with Doolittle's eyes? To my notion these colors are the same as those given in the Standard Dictionary, the latest and best in the English language, under the heading of 'Spectrum.' Strictly speaking, the yellow on the Italians is not exactly yellow, but leather-colored; but when we use the term 'yellow' we usually mean it in the broadest sense, and that may mean from a leather color to a lemon yellow. To say that Italian queens and bees do not have any yellow on them is to pervert the word from its ordinary accepted meaning. We say that the sun rises in the morning. While the statement is not correct, the phrase has an accepted meaning; in the same way, yellow, when applied to Italians, conveys an impression to the average person that is not misleading."

I have no extended remark to make, but I trust Mr. Doolittle will gratify my curiosity by answering a question. I don't remember ever seeing Italian bees called maroon until the present, and there was nothing original in my calling them yellow. Now, Mr. Doolittle, if you knew them to be maroon, while all the authorities, the books, and the bee-journals, were calling them yellow these years and years, will you be kind enough to tell us why you never mentioned it before?

McHenry Co., Ill.

Riding Hogs'-Backs—Southern California Apiarian Conditions and Prospects.

BY "THE RAMBLER."

THE above seems to be a sort of an undignified performance for the Rambler, and, indeed, it would be, under the common interpretation of the words. But when we speak of hogs'-backs in this country, there is a variety to select from, and even the most dignified man might mount one of them without so much as ruffling the frills of his dignity.

It is now mid-day, and hot as fury in the sun, and I am sitting in a chair and leaning against a California walnut tree and enjoying its shade. The bees in the apiary close by are humming a hot-weather tune. In yonder clump of bushes a mourning-dove is cooing to its mate, a mocking-bird is shouting and whistling in a sycamore tree, and a blue-jay is trying to be neighborly by picking the crumbs

from my table which stands in the open air. To my left, a canyon leads off to the west; to the front a larger one leads off to the north, and this is subdivided into many other smaller ones. As a consequence of the division of the land into so many canyons or ravines, there are a great number of ridges between them, some of them are quite sharp, with hardly enough room for a person to walk. These ridges are called "hog-backs," and when we explore these mountains it is always much more comfortable traveling on the hog-back than it is in the depths of the canyon, for there we find all manner of underbrush and obstacles.

This has been a sort of an alas season for California bee-keepers; our bees are making a precarious living, and one after another of our hopes of a honey crop have been blasted. We hoped for a yield of honey from the sage, which was in profuse bloom, but the fogs from Old Ocean kept hanging over us with their cooling influence until the bloom past, and then when the sun did exercise its prerogative of shining it was too late for the bees to get any honey.

Sumac is now coming into bloom, and our hopes are reviving again, for the buds are set very plentiful, and the few that are out are immediately visited by the bees. Wishing to explore the extent of the sumac pasturage I set out one morning for that especial purpose. I followed up the larger canyon to the north, and in the lower depths of it, where there was much shade and moisture, the bees were at work upon the wild heliopsis. This is a valuable honey-plant, for it is a profuse bloomer, and holds its flowers for a long time. There is a good amount of pentstemon—a trailing shrub, and having brilliant scarlet flowers; the tubes of these flowers are too deep for the bees to reach the nectar below, but there is another variety with white blossoms that are the proper length for bees to find the nectar, and I have an idea that the propagation of this variety would be a good scheme for bee-keepers to undertake.

I now climb up an abrupt trail, taking hold of the bushes to aid, and soon find myself upon the lower end of a hog-back. The first thing that attracts my attention is a brilliant spike of white flowers, and I can now see dozens of them scattered over the sides of the mountain. They look like plumes, tho quite rigid against the influence of the wind. This is the yucca or Spanish bayonet, and I do not wish to get too near it for the needles with which the lower portion of the stalk is armed are not agreeable to run against. Some species of it are credited with secreting a large amount of honey, but these specimens, and especially in this dry season, have not a drop of honey in them, and the bees did not notice the pretty and fragrant flowers.

Wild buckwheat and deerweed, or commonly known as wild alfalfa, abounds more or less upon the mountainside, but the bees are shyly working it, which shows that there is but little honey in it.

I am now well up to the top of this hog-back, and before I cross over to another let me sit down here and rest, and take in the scenery. Looking to the southwest I have the Cabuenga valley before me; it has recently been shorn of its grain, and there is nothing but stubble-fields surrounding the buildings on these great ranches. A little later a vile weed—variously known as flea-weed and vinegar-weed, but the true name is "blue curls"—will come in quite plentifully. Bees gather much honey from this, and it is a very low grade of honey, but it will be welcome this year, for it is as good as any honey for the bees to winter upon.

Before the advent of the Anglo-Saxon with his enterprise, these valleys were the best bee-pasturage in California; the sage here found a depth of rich soil for its growth, and the plants were vigorous, and yielded a greater amount of honey than the plants which grow upon the barren hillsides. That was the condition of the honey-pasturage in the early days when Mr. Harbison came to this portion of California and obtained those wonderful yields of honey. Now, the bee-keeper is thrust back to the hills, and the valleys are under cultivation.

Beyond the valley is a broad expanse, and it looks like a vast blue plain, and sky and plain merge together in the far distant. With a glass to aid our vision the plain would appear to be greatly troubled, and white crests would roll over it. Why, certainly, I see what it is now, it is the grand Pacific Ocean. It is six miles from this point of vision.

A little to the south we see Catilina Island, 25 miles from shore. It was here that Mr. Wood, of Michigan, proposed to establish a queen-breeding station some years ago, but one of California's poor seasons nipt the enterprise in the bud. I do not have much faith in island-reared queens myself, for just as good queens are reared on the main land now. So many localities are so thoroly Italianized that the

isolation from other races is as thoro as tho the breeding-queens were on an island.

We will now cross over into Laurel canyon. Here is a deserted cabin, the window gone, and the door hanging by one hinge. From the number of old, rusty tin cans around the door it is a deserted bee-ranch, and weeds are growing where the hives once stood.

Laurel canyon is inhabited to a certain extent, and here we run against a Chinaman's ranch. It is neat and clean, and with an infinite amount of labor he is raising vegetables for the Los Angeles market; but there are no bees here, and there are but few Chinamen that take to bee-keeping.

Up another branch of Laurel canyon I find another deserted cabin. The failure of the owner to find water led him to abandon it, and it is even more deserted than the bee-ranch below. The building is more or less a wreck. But here I find something that pays me for all my climbing—here in a secluded place is a bush in full bloom, and the bees literally cover it; hundreds of bees are on the flowers of this one bush. The flowers are in clusters, very small, and greenish white. It is the California coffee. The only one I ever saw previous to this was when I first came to California, and near the home of Mr. Arundell, of Fillmore. I think it is a rare shrub, and it is doubtful if any one knows the quality of honey the bees secure from it, but the fact that bees work upon it with such vigor in a dry season proves it worthy of a closer acquaintance and propagation. The gum-tree is receiving much attention as a honey-producer, why not include the coffee-shrub?

I am on another hog-back now, and our journey is homeward. But, look out! Whi-r-r-r-r! That is a rattler; hit him with a club! There, he is done for now. Take his rattles for a trophy. Two before this have been killed this year within half a stone's throw of my apiary.

I am now on the spur of the mountain above the buzzard's roost, and can look down upon the apiary, and a very good appearance it makes. The shade and the little tent look very inviting, and after a few minutes scramble downward we have made the circle of several hog-backs, and are at home again. I found acres of sumac, and wherever it was coming into bloom the bees were present. This gave me encouragement that some honey would be gathered from it. Honey-plants of all kinds, in order to make them do their best at honey-secretion, need the moisture below as well as above. Only about ten inches of rain in two years leaves the conditions below very dry, and while we live in hopes for some honey in the immediate future, our hopes are mostly stayed upon the glorious rains that will come to refresh the plants for another year.

Los Angeles Co., Calif., July 3.

The Bee-Hive or the Man—Which?

BY G. M. DOOLITTLE.

A CORRESPONDENT wishes to know if he had not better change the hives (Langstroth) he is using for the Hoffman, and gives the reason for thinking of such change, that he is informed that the Hoffman hive will give more honey than any other hive in the world. And this is only a sample of many letters which I receive, and from such letters it would appear that many think, to procure the *best* hive—a *hive* which will give "*big results*"—is all one has to do to reap a rich reward, with a few bees in such a hive. I have reason to believe, from the letters of the past, that thousands believe that all one has to do is to procure a Langstroth, Gallup, Heddon, Quinby, Hoffman, Dauzenbaker, or some other highly-recommended hive to meet with *certain success* in apiculture; no matter how little thought is given to the field, location, or securing the bees in time for the honey harvest, or how poorly attended to, if we have only a good hive we certainly shall have honey!

From the many failures in the bee-business, and the shipwreck ending in disaster of so many who started out joyously when embarking in the business, it would seem as if they depended simply on using, or having in their apiary, *good hives*. While a good hive has very much to do with the results of bee-keeping, the *man* has *much more* to do with success or failure, so far as dollars and cents are concerned.

Does a man buy a choice lot of Jersey cows, put them in a lot enclosed with a beautiful fence, with a nice watering-trough, painted off in ornamental fashion, and then leave them to take care of themselves, expecting a large profit from them? No. The man spares no pains in caring for and milking them, and gives them every chance in

his power which will tend toward success, realizing that upon *himself* lies the element of success or failure with those cows. Yet, ten to one, this same individual, or many very similar to him, will expect a large income from the same number of colonies of bees if they only have them in good hives, no matter whether they do anything for them once in three months or not.

The *idea* that "bees work for nothing and board themselves" must be banished from our thoughts before we secure much profit from them, and yet this very idea seems to take possession of very many when they embark in the bee-business. *Work*, for a man with brains enough to know that he must leave no stone unturned that tends toward success, is what *successful* bee-keeping means. A good hive in the hands of such a man is a power which can be used to roll up tons of honey, and show to the masses of the people that there is money in the bee-business. *Such* a man will have his bees in readiness for the honey harvest whether that harvest comes from white clover, basswood, or fall flowers, and such an one will do things in just the right time to secure the best results.

I am often asked, "What advantage has a movable-frame hive over a box-hive?" *Much*, every way, in the hands of a skillful apiarist, but none at all with the man who does not take advantage of its principles, or of the benefits derived by a judicious use of the same, such as knowing in the spring that each colony has sufficient stores to last till the flowers bloom, or in the fall that it has plenty of stores for winter, or that each colony has a good, prolific queen, or giving stores to the needy by taking them from those having an abundance, etc. What are the movable frames good for if not for the above purposes? And yet we have those all over the world who do not take a frame out of a hive once in a year, yet call themselves bee-keepers, and wonder why they do not succeed in securing as much profit from their bees as do some of their more successful neighbors! They have the same hives—that they made sure of at the start. They are like some persons I know of who, when asked how the bees are prospering, say, "Pretty well, I guess; they were about as heavy as I could carry when I last lifted them;" and upon being asked when that was we were informed that it was on some cool day in early spring when there was no danger from stings. If a hive is only *heavy*, that seems to be all that is needed to insure a *good* crop where the bees are in *good* hives, for these persons do not believe in "fussing" with bees as some do!

Thus we find plenty of bee-keepers, or those calling themselves such, all over the country. Is it any wonder that we have so many ready to tell us in a few years after they start in the business, that "bee-keeping does not pay?" These persons do not seem to realize that it is just this "fussing," as they call it, which makes the success of the prosperous ones.

I do not want it understood from the above that I think that a person is to be continually overhauling hives that they may be successful. Those who have read my writings in the American Bee Journal during the past know that such is not the case. No, not that. What I mean is, that when a *gain* is to be made by looking inside of a hive, *do it*, and do it at *just the time it will be to our best advantage*.

Attend to the bees in the spring in *just the right* time; put on the sections at the right time; see that all colonies have good, prolific queens at the time such prolificness is needed the most; and so on with all the work in and about the apiary. Do not keep more colonies of bees than you can care for, and have everything done in good order. Better results can be secured from 50 colonies properly attended to than with 150 colonies left to themselves.

Just what I wish to impress on the mind of every one who reads this article is this: That a thoro, practical apiarist will succeed with almost any of the frame hives now in use, while a careless, "go-as-you-please" person will not pay expenses with the best hive ever invented; and it is for the reader of this to know to which of these classes he or she belongs. If to the latter class, one of two mottos should be written in great big letters and placed where it can be seen at all times: "REFORM, or "BETTER GO OUT OF THE BUSINESS." Onondaga Co., N. Y.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

THE AFTER THOUGHT

The "old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

THE OLD HOME VS. THE NEW.

How much nicer the old home of Cyula Linswik is than the new one! Pages 353 and 354. So much of our progress on earth, in some mysterious way, seems to lose for us more than it gains. When the Kingdom comes on earth I reckon people will live half the time in little booths made of the branches of trees. (In Eden they had absolutely nothing at all for house—blue sky for one royal tent—and life one endless childhood). Upon the advent of *sin* it was that God in mercy allowed us to load ourselves up with labor-compelling humbugs, to keep us out of mischief.

And how mad I was to find out, for the first time, that Cyula Linswik is not a real name—folks who live in glass houses have such an itch to throw stones.

A SERMON CRITIC CRITICISED.

Mr. Whitney, in criticising the sermon of Mr. Tichenor, rather gets into the familiar role of "sinful scoffer." That sermon, however, is open to criticism, and would be a good one for somebody to criticise in a spirit of friendliness, and of love for the actual truth, no matter who gets pinched by it. Page 355. A farmer near me began bee-keeping recently. His cash expense was, I think, two or three dollars (instead of the Whitney minimum of \$10). Got quite a bit of surplus honey the next season—crosswise of the sections—and didn't take it off till the following June. That loss balance of \$3,240,000 would simmer somewhat, I imagine, if adjusted to actual experiences.

"WILL I BE MIST WHEN I AM GONE?"

In my own familiar nest, page 356, I see—"Mist him that time." The meaning of that looks rather misty.—When I am dead and gone shall I be *mist*? Rather too ambiguous logically, and theologically.

KNOWING EACH COLONY IN THE APIARY.

That good husband, on page 357, I am at a loss to know whether he needs a club, or a bottle of the "Balm of Sympathy." Does he pocket the profits of his wife's apiary? or does she instantly spend 'em for a new hat, and leave him to buy the apiary supplies? The most startling thing in Mrs. Stow's essay is the assertion that the bee-keeper should know every colony as he knows his own family. Pretty lofty target for us to aim at. Not necessary to suppose that she herself fully reaches it. Those who call our attention to high ideals *without* fully reaching them serve us a good term, sometimes.

DRONE-REARING IN CONNECTION WITH QUEEN-REARING.

I note that the excellent queen-rearing article of John Bodenschatz, page 358, follows the old regulation scheme of providing choice drones—a scheme rotten and self-defeating, it seems to me. Suppress the drones of the non-approved colonies (yet they *will* rear a few and *pamper* them), and cause the approved colony to rear hundreds of extra drones—with the inevitable result that they will be shabbily treated at home, and not one of them will be on time at the vital moment till a better groomed male has "got there." Worse than waste of time to stimulate drone-rearing beyond the bees' own inclination, unless we are also willing to take the time to secure the young drones homes, a few in a place, in colonies having few or none. Bee-keepers are keen-witted in most things, why can't they have common-sense in this matter?

GERMAN-ITALIAN BEES FOR COMB HONEY.

There must be something still much to be desired in our craft when both the Bee-Keepers' Review and Gleanings in Bee-Culture can soberly countenance putting on extracting-supers, and then taking them off to put on sections. All this to get bees *started* above. A good strain of German-Italian hybrids will start at once (when there is any surplus coming) with no more inducement than a couple of bait sections. Why not keep just such bees, if comb honey is what you're after? Page 361.

HUMAN NATURE AND HONEY-DEW.

How much human nature there is in the D. M. R. clipping, page 366. Having satisfied himself that some honey-dew exudes directly from the leaf (as the editor of the British Bee Journal has announced himself satisfied) he now wants to put up \$5.00 that there isn't any other kind.

NOTRE DAME DEVICE—HOUSE-APIARY KINK.

If I get the correct idea of the Notre Dame wintering device (page 369) it accomplishes nothing for the winter's good except to close the spaces at the ends of the frames—good as far as it goes, but hardly sufficient to account for such results as reported, one would think. The amount of difference we see between a box-hive and a good frame hive as to wintering helps us to a judgment in this direction. Probably excellence of packing and some other things contributed largely to the final result. It is certainly a remarkable result to realize 24 sections of surplus, with a total gain of 60 pounds May 6, on the north line of Indiana. The weights given indicate very large hives. Perchance we have rather a triumph of the large brood-chamber, kept so all the year round, than ought else. Note also that the one which last fall was 35 pounds live, and 41 pounds contents by May 6, had regained the winter loss and 72 pounds more! One would almost suspect that these bees, unknown to their keeper, had had opportunities for wholesale robbery somewhere.

In the same article Mr. Chrysostom contributes one of the excellent little kinks which cost but little and amount to much. Attach to each corner of the octagon bee-house board projections, extending out three feet or so, making its horizontal section look like a paddle wheel. The effect of this is to isolate the colonies on one face from those on the adjoining faces.

FEARS TO COMMENCE COMMENTS.

Guess I'll skip the Doolittle article, on page 370—not by any means because unworthy of comment—but you see if Dr. Miller comments on his questioner, and Doolittle comments on Dr. Miller, and I comment on Doolittle, and the editor comments on me, we shall have a "House that Jack Built," or a "Kid that Wouldn't Go," or something.

Glad to hear that a quart of bees *can* be made to rear a good queen, however.

BARRELS VS. TIN CANS FOR HONEY.

On page 371, C. P. Dadant gives us a model article in defense of our gawky country cousin, the honey-barrel—fighting on the losing side, I reckon, but fights well. He didn't explain how a *glue-coated* barrel could have its staves spread and closed again and yet be as proof against honey-soaking as before. How easy it sounds to say, "Spread the staves a little and lift out the head!" and how provokingly stiff and contrary those staves can be when inexperience tries the spreading and lifting! After a long time spent in disagreeable skirmishing you'll forget and rest a portion of your weight on the head—down in she goes, ker-squish! Still no peaceful solution arrives, nor will the head come out any better than before. Before you get it out and laid on the shelf it is in two pieces, and various little "do-funnies" the cooper put in shed out from between them. O, it can be done, but I don't like to do it.

That was a good shot at the 60-pound can—must be washed, and then it rusts inside. Very likely; but, then, original sin might tempt us to set it on a warm stove until dry as a toast. Some would doubtless rather empty one barrel than eight square cans; but I think they would mostly be persons accustomed to the former and not to the latter. That there is no taking out and putting back in the use of cans, is a strong point in their favor. Cans rather need a special heating arrangement to liquefy in them; while the barrel calls for kettle-room or pan-room enough to hold a barrel, and these pans or kettles would far better be water-jacketed. One set of utensils required is about a fair stand-off for the other, I take it. He was honest to tell us that we must not put the honey back hot if the barrel is used.

DYING YOUNG AFTER LIVING LONG.

And so Dr. Miller would die young, after having lived a good many years—pretty good ideal. Page 374. Still our efforts to *compel* our old and weary hearts to be lively about something, when they don't want to be, are oft a trifle sad. Doubtful if that is really the best way. Simple rest in the bosom of Him who hath eternal youthfulness may work better than forced skipping around. COGITATOR.

CONVENTION PROCEEDINGS

Report of the Chicago Bee-Keepers' Convention.

BY HERMAN F. MOORE.

THE fourth regular meeting of the Chicago Bee-Keepers' Association was held June 1, 1899. The attendance was small, considering that the secretary mailed about 250 invitations to bee-keepers in and near Chicago. Attention was called in the notice to a donation of \$9.00 which the association had received. This sum was to be used in paying a year's dues for the first 18 bee-keepers joining after the receipt of the notice. In such a case, 50 cents from a new member pays two years' dues. Some new members were received at the meeting.

In spite of the small attendance, the discussions were very interesting, and participated in by all present.

The committee on resolutions reported for consideration a resolution inviting the United States Bee-Keepers' Association to meet in Chicago in 1900; a resolution urging all our members to join the United States Bee-Keepers' Association; a resolution thanking Mrs. Stow, Mr. York and Mr. Moore for their present of \$9.00, and for the able manner in which they represented the bee-keepers before the United States food investigation committee. The said resolutions were all unanimously adopted.

The association discussed at length the question of amending the constitution. The following amendments were proposed, and the secretary was instructed to give notice of the same to all members, according to the constitution:

Amendments: Strike out the clause which reads, "Only bee-keepers resident in Cook County are eligible to office."

Amend Art. III, making the membership fee \$1.00.

Amend Art. VII, making times of meeting "first Thursday in April, and first Thursday in November."

Amend Art. V, changing word "December" to "November," for election of officers.

On motion, it was ordered that the September meeting be devoted to amending the constitution only.

"Our success in wintering" was now made the subject for discussion. All the members reported heavy losses, some more than half. Honey-dew stores seemed to be the cause in a number of cases.

Mr. George W. York address the meeting on the work of the Senate pure food committee. He was of the opinion that the information collected by it will be of the greatest benefit to bee-keepers everywhere.

Mr. Edward N. Eaton, a well known chemist and specialist in honey analysis and investigations, also address the association in an interesting and acceptable manner.

A paper was read by the secretary on current topics, and, on motion, it was ordered published.

The association then adjourned to the September meeting.

HERMAN F. MOORE, Sec.

Mr. Moore on Current Bee-Topics.

Your secretary has been requested to address you on current topics of special interest to bee-keepers, and especially to our own Chicago Bee-Keepers' Association. This is the day of organizations (wisely or unwisely), and bee-keepers must organize, and, being organized, carry out the best and largest plans for their chosen vocation.

The pure food investigation recently had in our midst, by the United States Senate committee, must be productive of much good. The people will awake to the necessity of legislation that shall require truthful labels on all articles of food, and the absolute prohibition of injurious chemicals or adulterations. Doctors, chemists, pharmacists, merchants, manufacturers, apiarists, etc., one and all recommended the enactment of such a national law.

You will see at once the necessity for it, when told that the investigation showed a very large part of all pepper sold is ground buckwheat hulls; ginger is ground tarred rope; flour is ground stone and clay; powdered sugar is cornstarch; butter is tallow and lard; lard is cotton-seed oil and paraffine; horse-radish is turnips; and three-fourths of the alleged liquid honey on the retail market is composed partly of glucose.

John Ruskin says: "I know hardly anything more

strange than that you recognize honesty in play, and you do not in work. In your lightest games you have always some one to see what you call fair-play. In boxing you must hit fair, in racing start fair. Your prize-fighter has some honor in him yet; and so have the men in the ring around him; they will judge him to lose the match by foul hitting. But your prize merchant gains the match by foul selling, and no one cries out against that. You drive a gambler out of the gambling-room who loads dice, but you leave a tradesman in flourishing business who loads scales! For, observe all dishonest dealing is loading scales. What does it matter whether I get short weight, adulterated substance or dishonest fabric? The fault in the fabric is incomparably the worse of the two. Give me short measure of food and I only lose by you; but give me adulterated food, and I die by you."

In the midst of all this pure-food agitation, we as bee-keepers, as representatives of a most honorable business, have a duty to perform both for our fellow apiarists and also for the general public—the consumers of our products.

Let us say that as for us, we henceforth set our faces, like flint, against the continuance of fraudulent adulteration of honey. Remember, that in this conflict with fraud and misrepresentation, the people are with us as a unit. The great people, the consumers of everything, are more suspicious than ever before of the food they are buying, and are firmly determined to know the real composition of everything they eat. This is only right and proper, for in many cases health, or even life itself, may be lost by inattention to these matters.

The United States Bee-Keepers' Association, with which most of you are perfectly familiar, has determined to stop all illegal adulteration, sophistication and substitution in the honey-business. This determination is most commendable, especially as we remember that half a million producers of honey and thirty-five million consumers of honey, as food and medicine, are directly interested in this question.

A very old saw runs: "Pay your money and take your choice," whereas too often people have paid their money for honey to find that the dealer had *chosen glucose* for them. The far-reaching effects of such a transaction may not be apparent to a careless observer. When a pound of unsatisfactory, fraudulent mixture is sold to a customer, a producer of pure honey has lost a sale of a pound of good honey. But more than this, the said customer, on finding his purchase unsatisfactory, at once objurgates all honey and honey-dealers, and eats no more honey in his family for a year. He would have purchast nine pounds more of good honey in the year; so that the sale of a pound of mixture (glucose and something else) has defrauded the honest apiarist out of the market for ten pounds of genuine honey. This is no fairy-tale. The writer can affirm the truth of the statement in the light of over ten years of close business relations with family consumers of real honey.

The United States Bee-Keepers' Association has now about 500 members. It is necessary that the number of members be increased to 1,000 before the aforementioned plans can be carried out to the fullest extent. It will cost much money and labor to prevent effectually the adulteration of honey. Many samples must be collected, many chemical analyses must be made and paid for, and the war against fraud must be carried on sternly for months, it may be years, before the enemy is finally beaten.

There is no way in which a dollar will go so far and do so much good as in paying a year's membership in the United States Bee-Keepers' Association to Eugene Secor, Treasurer, Forest City, Iowa.

Certain amendments to our constitution have been recommended for our consideration by the executive committee. One makes any member residing in Cook County or not eligible to office, and another changes the annual fee to \$1.00 a year. The executive committee realizes that in a great city like this, where both aims and expenses are high, the annual fee of \$1.00 each will no more than suffice to pay necessary running expenses. If the annual dues could be made \$5.00 instead of one, it would conduce greatly to sociability and the more effective protection of the interests of our members. An annual banquet and an annual picnic would be occasions of great pleasure to our members, and be the means of drawing tighter the fraternal bond.

It seems advisable for our association to extend an invitation to the United States Bee-Keepers' Association to hold their regular meeting in 1900 in Chicago. Their 1899 meeting will be held in Philadelphia, in September, which will, no doubt, be an occasion of much pleasure and profit to bee-keepers.

As citizens of Illinois, we rejoice that a pure-food law was enacted at the recent session of our legislature. This may be considered a step in advance, whatever may be the practical workings of the law. The much effort was made by a number of prominent bee-keepers of Illinois to procure the enactment of a foul brood law, it was unsuccessful.

It occurs to the writer that if the bee-keepers should ask to have as a clause, in a general law for their benefit, "funds for the enforcement and carrying out the purposes of this act shall be raised by a tax of five cents on each colony of bees within the State," such a law might easily pass.

HERMAN F. MOORE.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Keeping Down Increase.

Replying to Rufus Williams (page 429), he is probably right in his suspicion that the outer hives get some of the bees that belong to the central ones. At different times I've seen such a thing reported, and especially in Germany where they move their colonies to the buckwheat fields. Placed in long rows, the end colonies become strong at the expense of the central ones. I think this is more likely to occur where the bees are placed in an open space with little to mark their location except the hives themselves. That makes an additional argument in favor of having hives under trees. Aside from the comfort of the shade for the bees, and especially for the operator, the trees give a chance to mark the locality of each hive so that bees are not likely to enter the wrong hives.

I would like to ask Mr. Williams if he doesn't find pollen in some sections by the plan he mentions on page 429. Also what proportion of his colonies swarm again.

C. C. MILLER.

Dividing a Colony.

I lost a swarm of bees last winter and I took your advice and put the hive under a strong colony, and it did not work just as I thought it would. So I come to you for advice again. When I examined the hive the queen had taken possession and it was full of brood, so fearing making a mistake I put it back again. The question is, How am I going to handle these hives? Will it be necessary to buy a queen? If so, when would be the best time to part the hive bodies? I took the frames out of the bottom hive but could not find the queen, but as I have not had much experience with bees I was afraid I would miss her. What do you think of this plan? Take out the bottom hive and put the top hive on the stand; take out the frames of the hive that was under, and brush the bees off from the frames in front of hive, and let them go into the one on the stand; then move the hive with all of the bees to another stand, and put the hive that was on the bottom on the old stand, then give them a new queen. If this plan will work, when would be the best time to do it?

IOWA.

ANSWER.—You could hardly have had anything better than for the queen to go down and occupy the lower story with brood, for she wouldn't do that till it was full above, and without the lower story she would have been cramped for room. If you are working for extracted honey, there's no need to take away either story. Just put on the extracting-super as a third story, with an excluder under it, and you are all right. If you have only one size of frames, take one of the frames of honey from below and put in the third story to give the bees a start. If you think the queen will have enough room with one story, put an excluder between the two stories, putting all the brood in the lower story, and

if there's too much brood to go into one story and you have no other use for the brood, then put in the upper story the brood that is most sealed. Be sure that the queen is in the lower story, and if you don't find her, after you have the excluder on the lower story, brush off in front of the entrance all the bees from the combs in the upper story.

If you are working for comb honey, it will hardly do to leave the two stories. Take away one story, filling into the story that is left all the brood you can. If there is a surplus of brood, you can use it for strengthening weaker colonies or any other purpose.

The plan you propose will work if you don't lose the new queen, but being inexperienced there is some danger you may not succeed in introducing her. You will probably have less trouble introducing if you leave the queen on the old stand, setting one story on a new stand, and giving it the new queen next day after making the change.

Laying Workers and Drone-Brood.

This is my first season with bees. I have nine colonies, most of them bought and moved the first week in May. Two swarms issued and got away a few days after being moved. Not being informed on what procedure to follow, without then knowing from which hives the absconding swarms issued, I went thru several hives and cut out all queen-cells. Two cells taken from one hive hatch queens the same evening while I had them on the table examining them. A few days later I discovered the colony from which these cells were taken was queenless. It was very strong in numbers, the bees 3-banded Italians. Cells were cut out perhaps 15 days ago. Now I find some thousands of cells containing larvae in all stages, some capt, and all new comb built drone-comb containing one to four eggs in each cell. I hooted over 400 larvae out of cells, but the work being too slow I gave it up as a bad job. The bees have stored pollen liberally and some honey in the combs.

I have just secured a fine, young, supposed-to-be laying queen from a queen-breeder, and placed her under a cage about 3 1/2 x 5 1/2 inches on one of the combs containing hatching brood. Brood is hatching in her cage, and I placed some 30 just-hatched bees with her under the cage. This is prest down tight on the comb so that no bees can get out or in, and I expect the old bees to accept the queen in two or three days.

Please advise what is the best course to pursue regarding the combs so filled with the larvae of laying workers, for previous to the laying workers commencing laying I found there was not a larva or capt cell in the hive—this about the time I cut out queen-cells.

I have taken out the four combs containing the greatest amount of larvae and placed, with adhering bees, in an empty hive adjoining the bees' own hive, expecting the workers will leave the comb and go home, and that the laying workers will stay, and I can kill them. But there will be thousands of dead larvae in the combs, and I dislike to waste the combs. Would the dead larvae produce any disease if the combs were returned to the bees? or what is best to do?

NEBRASKA.

ANSWER.—Take the combs of drone-brood and slice off the heads of the sealed brood with a sharp knife, dust fine salt on the unsealed brood, and distribute the combs to colonies having laying queens. They'll clean them out at a cheaper rate than you can. Don't be too much discouraged if you find your queen has not been kindly received, for bees with laying workers are inclined to be stubborn about accepting a queen. It is now believed that where laying workers are present they are present in large numbers, and perhaps they don't like the idea of giving up their job to some newcomer. As a general rule it doesn't pay to try to continue a colony that has laying workers. The workers are all pretty well advanced in age, and the best thing is to break up the colony and distribute combs and bees among other colonies.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

The Premiums offered on page 442 are well worth working for. Look at them.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,
15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39. JULY 20, 1899. NO. 29.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Introducing Queens. Editor Hutchinson says a caution is needed in regard to introducing queens by the method described on page 435. "Don't use newly-built comb for caging the queen upon its surface, as the bees may burrow under the edge of the cage, and kill the queen. Such a case has been reported recently. Of course, this trouble might not happen once in fifty times, but it is just as well to use old comb and thus avoid this fiftieth time."

"The Honey-Bee: A Manual of Instruction in Apiculture, by Frank Benton, M. S., Assistant Entomologist," is the full title of Bulletin No. I, New Series, issued by the Division of Entomology of the United States Department of Agriculture. We have just received a copy of the third edition, presumably thru the kindness of Mr. Benton, who, in the American Bee-Keeper for July, calls attention to some of the most important changes from former editions, in these paragraphs:

There have been slight changes made for this edition, only such as seemed quite necessary, as the pages were all stereotyped when first published. Chief among these is the change of the scientific name of the honey-bee, *Apis mellifica* to *Apis mellifera*, the older synonym, which, in accordance with the rules of zoological nomenclature, takes the precedence. As this name goes back to the tenth edition of Linnaeus' "Systema Naturae," 1757, there will not be a further change, but *Apis mellifera* will stand as the name. The change will be made wherever the name occurs in

Bulletin No. 1. Two or three additions to the list of honey-plants are made, and several changes in dates of blooming in different localities. The following has been inserted on page 64:

"The great value of bees as cross fertilizers makes their destruction a serious injury to the interest of fruit-growers; therefore spraying with arsenicals during fruit-bloom should never be practiced. The injurious insects can be reached quite as well before and after the blooming periods."

The Simmins non-swarming system is better elucidated by an added reference to the necessity of employing drawn combs in the super—a feature too often overlooked in connection with the method brought forward by Mr. Simmins, and yet one which is essential to its complete success.

This Bulletin No. 1 is intended for free distribution, but we understand that the edition issued July 1, and consisting of 1,000 copies, is practically exhausted already. In all now there have been 22,000 copies of the pamphlet published and sent out in the interest of apiculture. Applications for a copy can be made thru congressmen, or direct to the Department of Agriculture, Washington, D. C.

Sweet Clover a Help to Good Roads.—From the way in which sweet clover is so commonly cut down along the roadside while weeds of all kinds are allowed to grow, one would suppose that no weed can be so bad for the roads as sweet clover. C. H. Dibbern makes in Gleanings in Bee-Culture a revelation in this regard. So interesting and so important are the facts he gives that they warrant a very full quotation from him, as follows:

Last July, while driving in a distant township I struck a piece of road that was a pleasant surprise and a revelation to me. Evidently some bee-keeper must be road commissioner, or else he had learned something. Here, as in so many places in Illinois, the sweet clover was growing luxuriantly on both sides of the road. By running a mower up and down the road several times during the summer it had been kept from encroaching on the driveway. Not only that, but the cut clover had been thrown into the middle of the road; and how springy and delightful it all was! There was no dust, and the pleasant perfume of sweet clover filled the air. Some cattle in an adjacent pasture were reaching thru the wire fence and feeding on the clover within reach; and the bees were on hand by thousands, carrying away the nectar and filling the air with their contented hum. Soon I past into another township; and, tho the sweet clover had extended for miles further, it had all been cut and burned in the road, leaving a scene of desolation; and, oh, how dusty it was!

Again I past over this road in October. I had been wallowing thru the mud, and was weary enough, when I again experienced the pleasant sensation of my sweet-clover road. Instead of mud there was that springy road-bed, without mud or dust. Upon further investigation I found the sweet clover had all been cut when about done blooming, and carefully piled in the road where the sun had soon wilted it, and the wagon-wheels had crushed and mixt it with the soil. Tho this road ran thru a level, mucky country, it was the best road there was anywhere. The millions of decaying roots in the ground on either side seemed to provide a sort of natural drainage that seemed to carry off all surplus water. It appeared that no work with plow or grader had been done on it for several years, and only the intelligent care of the clover had done the business.

And so new values of sweet clover are being discovered all the time. But just read the following notice, which was issued by a thistle commissioner in Antioch, Ill., under date of June 20, 1899:

Notice is hereby given to all property owners in the town of Antioch, to cut all Canada thistle, *sweet clover*, and weeds to the center of the highway growing on their lands; also all other *noxious weeds* found growing upon their lands or upon the highways, before allowing same to mature seed. All persons failing to comply with this notice will be prosecuted under the statute made and provided.

THISTLE COMMISSIONER.

We have italicized some words in the above so that they will be particularly noticed. It will be seen that sweet clover is clast with noxious weeds, tho there is no law in

this State classing it, we believe. We would suggest that the bee-keepers in and around Antioch get after their "commissioner" with a big bunch of thistles and compel him to let sweet clover alone until he learns something about its many values.

Thursday, July 6, we took a bicycle ride some 30 miles northwest of Chicago, and the sweet clover was coming into bloom in immense quantities, and the bees were just roaring on it. But, actually, some ignoramuses who control the roads and the railroads in that region were mowing it down just as fast as they could. What a pity it was, to see all that fine stock feed and nectar for bees destroyed! If it must be mowed, why not wait until September, or later? Of course, by that time the seed will have matured and fallen on the ground to grow again, but what of that? If sweet clover were not growing there, doubtless some miserable weed would be, and is it not much better to have the rich, fragrant, nectar-laden sweet clover along the roadsides than ragweeds and other kinds of noxious weeds?

We do hope that our readers everywhere will inform themselves as to the varied values of sweet clover, and talk it up until its enemies cease to cut it down, and thus destroy one of the best plants our country affords—for stock pasturage, for bees, and, lastly, for the making of good roads, as Mr. Dibbern has shown.

Apis Dorsata in the United States.—An editorial in *Gleanings in Bee-Culture* is headed, "Apis Dorsata Here at Medina at Last; Giant Bees for Sale." The editor goes on to describe at length what beauties they are, each worker looking like a great, big yellow Italian queen, and after arousing to the highest notch the expectation of the would-be purchaser, he informs him that the bees will be sold, only one worker to each purchaser, at 10 cents each, *each worker being in a little bottle of alcohol.* Oh, Editor Root, how could you so trifle with one's feelings?

STENOG, in *Gleanings in Bee-Culture* for July 1, starts out his department with this rhythmical "pick":

"Bring out your guns, all you that has 'em,
And blaze away with enthusiasm!
The basswoods now their nectar ooze,"
Says Drone, "and we have not an hour to lose."

Just why the bees should bring out their "guns" instead of "honey-sacs," in which to collect the oozing nectar, we can't quite understand. But perhaps in Stenog's *locality* the bees use guns for that purpose.

MR. R. F. HOLTERMANN, editor of the *Canadian Bee Journal*, lost his little 6-year-old son Richard by very sudden death on June 12. We did not learn it until July 11—nearly one month later—or we would have announced it before in these columns. We are sure that our readers will join with us in extending to Mr. and Mrs. Holtermann sincerest sympathy in their great sorrow. Mr. Holtermann gives the following particulars in the July number of his paper:

"On Monday, June 12, after dinner, contrary to my usual practice, I remained at the house for some time. I felt like resting, and did what I do not remember of ever doing before at that hour of the day—I lay down in the hammock at the side of the house. Those who were at our house during the winter convention may remember the fair little boy, strong, and the picture of health. He came to me and I askt him if he wanted to go to a gospel meeting for children, and he said yes. We arranged that his older brother should take him on the wheel. Then he askt for

the hoe, he wanted to plant some radish; not ten minutes after I heard him crying on the other side of the house. I did not go for almost a minute. When I did go, his mother was with him, and he said he had pains in his legs. In about a minute he had convulsions. I said he was poisoned. In response to a question he said he only had what we gave him for dinner. I jumpt on my wheel and in ten minutes or so had one doctor, and in a few minutes another, but all was over in about half an hour. There is no doubt it was sun-stroke, as he had no hat on his head."

MR. G. M. DOOLITTLE, of Onondaga Co., N. Y., writes us that Providence permitting, he will be at the Philadelphia convention. A good many bee-keepers would be very glad to meet Mr. Doolittle, having read so much of his writings on bee-keeping.

MR. J. H. MARTIN, writing us from Los Angeles Co., Calif., July 3, had this to say about the discouraging conditions in Southern California:

"This is a season of utmost discouragement to bee-keepers here; there will be but little honey produced, and there will be a great loss of bees. Fifty percent died last year, and 50 percent, if not more, of the remainder will die this year. It will be some years before Southern California will recover from this disastrous condition of things."

MR. WM. A. SELSER, of Philadelphia, dropt in to see us, very unexpectedly, on Wednesday, July 12. Several years ago he called on us when passing thru Chicago, but, unfortunately, we were then out of the city, and mist seeing him. Mr. Selser is perhaps the largest bottler of pure honey in this country, having, we believe, disposed of some 30,000 pounds in that way thru grocers, in a single year. He is also an extensive bee-keeper, producing much of the honey which he sells.

Mr. Selser is expecting a large convention in Philadelphia, next September, when the bee-keepers "settle" there for a few days. He is an enthusiastic worker in the bee-industry, as well as a loyal and active Baptist in church matters. No doubt Dr. Mason (who is also a prominent member of the same denomination) will lay strong claim to Mr. Selser at the convention, but we'll try to do our part in seeing that the jovial Doctor don't monopolize him entirely.

MR. THOS. G. NEWMAN was given a call by "The Rambler," when the latter was in San Francisco, reference to which is thus made in *Gleanings in Bee-Culture* for July 1:

"I felt as tho it would not do to pass thru the city without shaking the hand of that staunch friend of the bee-keeping fraternity, Mr. Thos. G. Newman.

"Mr. Newman gave us a cordial greeting, but we were pained to find him in delicate health. When he first came to California he found an abiding-place in the extreme south, at San Diego. We were in hopes for a time that Los Angeles would become his permanent home, and there is not the least doubt in my mind but this city would have been the more healthful for him; but business matters necessitated the change to his present quarters.

Mr. Newman is an eminent spiritualist, publishes the *Philosophical Journal*, and but a few moments' conversation with him will demonstrate that he is a man who desires to benefit and elevate his fellowmen. He has been a faithful worker in the interests of bee-keepers, and there is no use to refer to the firmness of his backbone in reference to the affairs of the Bee-Keepers' Union."

It is now a little over seven years since Mr. Newman severed his connection with the *American Bee Journal*. For about 18 years previous to that time he had been its editor, and had carried it thru many trying years. While he never run the journal just for fun, it is true that he was, as *The Rambler* says, "a faithful worker in the interests of bee-keepers," unselfishly devoting his best efforts to the up-building and extension of the bee-industry.

When Mr. Newman purchast the *American Bee Journal* it was issued monthly, at \$2.00 a year, and had about 800 subscribers, while to-day it is published weekly, at \$1.00 a year, and has nearly ten times as many readers.

It will be noticed that before the reduction in price and change to a weekly, the *Bee Journal* cost its subscribers nearly 17 cents a copy; to-day it costs less than 2 cents. And yet some object to the present price; but such are not worthy of the name "bee-keeper."

Tin Cans versus Barrels.—Editor Hill, in the American Bee-Keeper, while conceding that others may use tin cans in preference to barrels, thinks it not amiss to say that he "has used a number of carloads of tin cans as a honey-package, and has found the percentage of loss thru leakage greater than where barrels are used."

Duff's Feeder is figured in "Alfalfa, Grasshoppers, Bees: their Relationship," and is very simple of construction. Take a two-inch soft white-pine plank large enough to cover the hive, bore it full of holes with a two-inch or smaller bit, letting the holes come not quite thru, except near the center where one or two may come clear thru to make passage for the bees. An upper story or a super is set over, thus protecting against outsiders.

Bees Consume More if Stores are Poor.—A Stray Straw in Gleanings in Bee-Culture says: "Do bees consume more stores when they have honey-dew? Some of mine starved with what I supposed were sufficient stores. [A few years ago, I believe, it was agreed that the bees would consume less good stores than of poor. Has there been anything to change that opinion? I do not remember.—Ed.]"

Duff's T Super, as described in the bulletin of Kansas University, differs from the ordinary T super in the construction of its T tin. Instead of this being a piece of tin folded in the shape of a T, a straight piece of tin is nailed on a strip of wood. The wood is $\frac{3}{8}$ -inch thick, $\frac{1}{2}$ -inch deep, and a little shorter than the inside width of the super. The tin is one-inch wide and $\frac{1}{2}$ -inch shorter than the wood, being nailed on the narrow edge of the wood. Thus the sections are held $\frac{3}{8}$ -inch apart by the wood, making less temptation for the bees to glue than when a narrow crack is left.

The U. S. Pure-Food Investigation is stirring things up lively at Chicago. Senators Mason and Harris and Prof. Wiley had Editor York on the stand for the greater part of one session, and he was well loaded with solid facts that were corroborated by H. F. Moore and Mrs. Stowe. The testimony will be printed in full in the report to Congress, and it will be nothing strange if some laws are enacted that will not make the way any smoother for adulterators. [The Pure-food Investigating Committee got hold of the right men; indeed, it could hardly have secured better ones. Let the good work go on.—Ed.]—Gleanings in Bee-Culture.

Foul Brood has been considered in a series of able articles by Prof. Henry W. Brice, in the British Bee Journal, and his final considerations are as follows:

1. Post mortem examinations show clearly that bees and queens are affected with foul brood, and while this is so no cure can be effectual that confines its attention to brood alone.

2. The present methods of dealing with affected hives and appliances are decidedly faulty, and in a great measure useless.

3. That while comparatively easy to destroy the bacilli, it is next to impossible (in dealing with live bees and brood) to destroy the spores of *B. alvei* without injuring the bees, other than by the only safe method of causing them to germinate.

4. *B. alvei* in the rod form is capable of being effectually destroyed if the process is properly carried out.

5. Chemical agents and drugs to be effective must be persistently applied, and the treatment constant, for at least three generations of the worker-bees and brood reared during this period.

6. Seeing that queens are in nearly every case affected, no treatment can be satisfactory and complete until colonies are requeened from a perfectly healthy colony.

7. The only perfectly safe method I know of for treating hives in which bees suffering from foul brood have been kept is to paint these inside and out with two coats of good oil paint, rubbing the same into every crevice and corner,

so as to stick down (as bees do with propolis) all spores beyond the possibility of their being ever again freed and finding a suitable medium for growth. It must be remembered that bacilli or germs of any kind are incapable of spreading beyond the frame in which they are isolated, whilst in a fluid state, unless carried to fresh pastures after contact with something else. Thus I contend that a spore stuck up against a hive wall in a sort of enameled case is practically sealed up, and impossible of removal under any ordinary circumstances.

8. Boiling is almost useless as at present carried out. In fact, I found it necessary to permit some time to elapse between successive boilings, to allow the spores to germinate between each operation. For this purpose a medium must be present of some kind, as without this even successive boiling of hives is mainly unsatisfactory.

9. In ordinary hands it is futile attempting to cure any but mild cases of the disease. It thus becomes both better and cheaper to destroy by burning. This may seem hard lines to some, but I feel convinced that in bad cases it is the only method worth consideration.

Queen-Breeding Delayed in the South.—Gleanings in Bee-Culture says: "Strangely enough, the queen-breeders of the South have this spring had almost no advantage over those of the North. During March and the forepart of April the weather was about as unfavorable for queen-rearing in the southern portions of our country as in the northern; and when the weather did open up warm and balmy, the queen-breeders in the North could begin just as soon. These thoughts came to me when we tried to get queens from the South this spring. The almost universal complaint seemed to be that the weather had been too unfavorable in the South."

Extra Honey Brings Extra Prices.—"Stenog" says in Gleanings in Bee-Culture that some remarkably fine honey was received by the A. I. Root Co. and offered at 20 cents per section of about 14 ounces (about 23 cents a pound.) It was all taken instantly, even at that price, and he thinks a large amount of such honey might be sold in the cities, to a certain class who care little what a thing costs so it suits them, at 40 cents a section. He adds: "Of course, not all can produce such honey, but so long as the poorest regulates the price of the best, just as the worst boy in school 'regulates' the morals of the rest, it behooves somebody to see that the poorer grades are improved."

Do Large Colonies Store More than Small Ones, in proportion to numbers? That's the question that is troubling two of our editors. Editor Hutchinson admits Editor Root's argument that a large colony can keep up the heat more economically, but thinks that rather an argument against large colonies, as the principal storing occurs when bees are driven out of the hive by the heat. To help settle the question, Editor Hutchinson, in the Bee-Keepers' Review, proposes experiments something like this:

"When two swarms unite in the air, give one-third of the bees in one hive and two-thirds in another hive, giving each a queen. Some of these swarms should be hived on combs, some on foundation, and some on starters, and results carefully noted."

Queen-Cells—When Should they be Given?—G. M. Doolittle says in the American Bee-Keeper:

"If I attempt to give a queen-cell to a colony from which I have taken a queen, before they start cells from their own brood, as a rule, the cell will be destroyed. Hence if, at 24 hours after the removal of a queen, no cells are started with me, it is not safe to give a cell just ready to hatch, unless the cell is protected with a cell-protector. As looking over the combs to see just when cells are started is extra work, I now wait 48 hours, or use the cell-protector at 24 hours (generally the latter), and all works well. The West cell-protectors, which are the best in the market, can be bought of any supply-dealer, or any one can make protectors by rolling wirecloth around a properly-shaped stick so as to form a cage having an opening in one end as large as a lead-pencil, while the other end is large enough to admit the cell at the base. The ripe queen-cell is now slipped into the protector, and the large end secured so the bees cannot get at it, when the whole is put down between two combs, where it is left to hatch. As the bees always destroy a cell by biting into the side of it, this protects the cell so they cannot do this, yet allows the queen to come out at the lead-pencil hole."

Root's Column

GLEANINGS AT REDUCED RATES....

We do not need to tell you about our journal, for it will speak for itself; but as an extra inducement we make the following low offers:

Offer No. A.

For 25 cents we will send GLEANINGS IN BEE-CULTURE from the time your subscription is received until January, 1900. If you send in your order promptly you will get 6 months for only 25 cents.

Offer No. B.

For \$1.00 we will send an untested Italian Queen worth 75 cts. and GLEANINGS IN BEE-CULTURE one year.

Offer No. C.

For \$1.00 we will send GLEANINGS IN BEE-CULTURE the rest of this year and all of next year, that is, from the time your subscription is received until January, 1901. The sooner you take advantage of this offer, the more numbers you will receive.

Offer No. D.

For 50 cents we will send GLEANINGS IN BEE-CULTURE 6 months beginning July 1 and Vol. I of Gleanings. This is for the year 1873. There are many interesting things. There are 12 articles on "Starting an Apiary," and while some of these may not be practical now, there is much valuable information and it gives a good idea of bee-keeping at that time. Our supply is limited and of course we cannot continue this offer long.

Old as well as new subscribers may take advantage of these offers, but all arrearages on back subscriptions must first be paid at \$1.00 per year.

ADDRESS

THE A. I. ROOT CO.
MEDINA, OHIO.

In the multitude of counsellors there is safety. Prov. 11-14.

Which for Honey Blacks or Italians?

Query 97.—If you wanted only honey and did not expect to sell queens or bees, would you change from blacks to Italians?—N. C.

- E. France—No.
- J. A. Green—Yes.
- W. G. Larrabee—Yes.
- Dr. A. B. Mason—Yes.
- Mrs. A. J. Barber—Yes.
- Mrs. L. Harrison—Certainly.
- G. M. Doolittle—Yes, yes, yes.
- J. A. Stone—Yes! by all means.
- J. M. Hambaugh—Most assuredly.
- Prof. A. J. Cook—I certainly should.
- Chas. Dadaut & Son—Yes, in any case.
- Rev. M. Mahin—I most certainly would.
- Dr. J. P. H. Brown—Yes, I would change.
- P. H. Elwood—Not unless in a buckwheat section.
- A. F. Brown—Yes, or at least to Italian-black crosses.
- D. W. Heise—If I could make the change at a very small expense, yes.
- R. C. Aikin—Yes. Italians are more pleasant to handle, not so wild, prettier.
- Mrs. J. M. Null—Yes, always. On an average they are worth twice as much as blacks.

E. Whitecomb—Yes. It is as necessary to infuse new blood in the apiary as it is in the herd.

Eugene Secor—I think I would introduce enough Italian queens to at least hybridize the apiary.

C. H. Dibbern—Yes; the best bees are what we want for gentleness as well as honey-gathering qualities.

C. Davenport For extracted honey I would; for comb honey, in my locality and with my management, I prefer blacks.

R. L. Taylor—I should not change to pure Italians, but I think some Italian blood in your blacks would be an improvement.

Dr. C. C. Miller—I want only honey, and do not sell queens or bees, and for many years I have worked to keep out black blood.

Adrian Getaz—I would depend upon how good the strain of blacks I might have would be. If satisfactory, I would not go to the expense of a change.

J. E. Pond—Yes, most certainly. Reasons in plenty could be given for this, and I know of no good reason for doing otherwise, at the present price of tested Italian queens.

O. O. Poppleton—My experience in Iowa, Florida and Cuba has shown me that this is a question of locality, but it is impossible to even skim the subject in the question column.

E. S. Lovesy—While I am not very anxious for the pure Italians, I would change from the blacks every time. The most unsatisfactory bee to me is the leather-colored hybrid.

Emerson T. Abbott—Not if I were contented with the blacks, but I do not like to handle them. The Italians will gather more honey, but the blacks will produce an article which will bring more in the market.

G. W. Demuree—I certainly would, in my locality. Italian bees protect their combs much better than do the black bees. A mere handful of Italian bees with a queen has been used in my apiary to protect a hive full of combs during the heated season. Black bees will retreat and yield before the moth until all is lost.

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |
|-----------------------------|-----|--------|--------|--------|
| Sweet Clover (melilot)..... | 60c | \$1.00 | \$2.25 | \$4.00 |
| Alsike Clover..... | 70c | 1.25 | 3.00 | 5.75 |
| White Clover..... | 80c | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover..... | 60c | 1.20 | 2.75 | 5.00 |
| Crimson Clover..... | 55c | .90 | 2.00 | 3.50 |

Prices subject to market changes.

Add 25 cents to your order, for cartage, if wanted by freight.

Your orders are solicited.

GEORGE W. YORK & CO.
118 Michigan Street, CHICAGO, ILL.

Northern Queens.

IF YOU want the best honey-gatherers, the longest-lived and hardiest Queens, try a few of our **Northern bred Italians**—"daughters of imported Queens." Tested Queens, \$1.50; untested, \$1.00; 2-frame Nuclei with tested Queens, \$3.00 each; the same with untested Queens, \$2.25. Correspondence solicited.

MATE WILLIAMS,
2644 NIMROD, Wadena County, MINN.

Bees by the Pound YOUR OPPORTUNITY!

We have arranged with a large bee-keeper in Cedar County, Iowa, to furnish ONE-FRAME NUCLEUS OF BEES WITH WARRANTED PURE ITALIAN QUEEN and ONE POUND OF PURE ITALIAN BEES—all for only \$2.00; or in lots of five at \$1.80 each. There are only 75 for sale. Better order quick if you want any. If more of the queens are wanted, these can be had at 75 cents. All queens reared by the Doolittle process.

GEORGE W. YORK & CO.

418 Michigan Street, CHICAGO, ILL.

Bees Doing Fairly Well.

Bees are doing fairly well in this locality. There is quite a crop of white clover, but not as profuse with honey as some seasons. I have 18 colonies, and have had no swarms as yet.
FRANK RUFFNER,
Shelby Co., Ill., July 6.

The Bees Like a Dark Color.

MR. EDITOR:—You ask on page 425, "Who was it that said all colors look alike to bees, and that they would not sting dark objects any more than they would light ones?" Well, I didn't, but I stand ready to prove that my bees can be handled without the least trouble by a person dressed from head to foot in black, without the least sign from them of annoyance, so far as color is concerned. In fact, I have had them out of the hives, the frames standing around me filled with bees, while thus dressed, and all this without veil or smoke. One cannot do this with black bees.
WM. M. WHITNEY,
Kankakee Co., Ill.

Poor Prospects for Honey.

This season we have not had one-half inch of rain for three months; everything is drying up. There is no white clover this season. I have 54 colonies of bees, and have had two new swarms. I have not taken one pound of honey in the sections yet. I have kept bees nine years, and this is the worst season I ever saw. I am afraid I will have to feed the bees for their winter supply. Basswood is just coming into bloom, and that will be our only hope of any surplus.

Queen-Clipping Device Free...

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. EXTRACTED HONEY

We are now in shape to buy Extracted Honey, either in large or small lots. Parties having any to offer will do well to sell to us, as Cincinnati is a great market for Extracted Honey. Submit a small sample, stating quantity, style of package, and price expected. Prompt remittances. References:

Western German Bank — The Brighton German Bank Co. both of Cincinnati, O.

27Atf Please mention the Bee Journal.

There is quite a good deal of sweet clover around here.

The bees were strong in the spring, and had lots of honey. They seem to be strong now, and ready for work, if there was any thing for them to do.

Last year I got about 1,600 pounds of honey. I sent a half ton to a man in Brooklyn, N. Y., for 12 cents a pound here. About 15 days after the shipment he made an assignment. I have never received one cent for any of it; so it will make two poor years for me—one by fraud and this season by the severe drouth.

There will not be any honey thru this season.

I think a good deal of the American Bee Journal. It comes to me regularly every Friday. I don't see how any bee-keeper can get along without it or some other bee-keeper. I have learned one thing in the Bee Journal this season that was worth the year's subscription. **GEO. H. ADKINS,** Essex Co., N. Y., July 1.

Not Much Surplus Honey.

June 1 we had from two to three inches of rain, so bees will live over in this vicinity. There will not be very much honey put on the market this season, and it will be about all consumed by the home market.

M. D. NICHOLS, San Diego, Co., Calif., June 19.

Bees Not Doing Much.

It is cold to-day and no sight for bees. They have been working somewhat at basswood and other things, but I fear not much more than getting a living. **E. E. HASTY,** Lucas Co., Ohio, July 5.

Very Disappointing Year.

We have had a very disappointing year with our bees—excessive cold in February and a continuous drought have ruined this year's honey-crop, except in a few favored locations. **CLAUDE STERT,** Uvalde Co., Tex., July 1.

Honey Crop a Failure.

The honey crop is a failure in this section of our country. **H. B. LAMBERT,** Simpson Co., Ky., July 8.

Not a Favorable Season.

We bee-keepers here in Christian County have had a very wet spring and early summer, and bees have not done very well. There is not more than one colony of bees here to where there were 10 five years ago. It seems as if we do not have the honey-flows we used to have. There was a good supply of white clover bloom, and the bees got enough to build up pretty well, but there was little swarming and no surplus to amount to much. There is now a good prospect for a fall crop of smartweed, if we have a season from now on. **G. G. LARGE,** Christian Co., Ill., July 10.

Basswood Slighted by Bees.

I have bees, also a couple basswood trees which have bloomed this year for the first time. The blossoms on them are big, luscious and fragrant. The bees are not more than 50 feet away from the trees, and yet I have watchd and waited hoping to see those bees literally swarm over those inviting, waxy blossoms, but not a bee have I seen on them. I expected they would fall over each other in getting there—but not a fall.

Now, why was this thusly? Do you suppose that nectar was too rich for their aristocratic blood, or was it just a trick of theirs to deceive me? I even took a limb with a fine lot of blooms, and put it right in front of their hives. No, sir! they wouldn't have it.

Well, for the life of me, I don't know what those Italians of mine do feed on this year. The few beads of white clover in the

Shipping-Cases!

We are overstocked on 12-pound and 24-pound single-tier shipping-cases; also 1-gal. Tin Cans, and 4-pound, 1-pound and 2-pound Glass Honey-Jars (Muth's); also Novice No. 5, and Cowan No. 15 Extractors for 2 Langstroth frames. We will make **FIRE SALE PRICES** to move above stock. **GET OUR PRICES AT ONCE,** as they won't last long at the figures we will offer them at.

Italian Queens

Rearred from the best 3-band honey-gatherers by Doolittle's method. Prices—45 cents each; 1/2 dozen, \$2.50; one dozen, \$4.50. **SAFE ARRIVAL.**

W. J. FOREHAND, 28A6t FORT DEPOSIT, ALA. Please mention Bee Journal when writing.

Golden Italian Queens!

5-banded Untested, 60 cts. each; Tested, \$1.00 each. 1-frame Nucleus, \$1.50 2-frame Nucleus, 2.00 3-frame Nucleus, 2.50 each, with untested Queen.

I am running 800 nuclei, and can send Queens by RETURN MAIL. I have no 3-banded queens, and no 5-banded drones in my apiary. Am making a specialty of rearing the 5-banded strain this season. My 5-banders are working on red clover. Queens are reared by Doolittle's method. I insure safe arrival of queens. This is a post-office money order office. Address your orders to

Dan'l Wurth, Falmouth, Rush Co. Ind. and receive fair treatment and prompt service. If you want 5-banded queens that are reared in a yard where there are no 3-banders, I am at your service. Parties wanting more than one queen will do well by writing for prices.

28Atf **DANIEL WURTH,** Falmouth, Ind. Please mention Bee Journal when writing.

The Novelty Pocket-Knife

(A heavier and stronger knife than the one we offered heretofore.)

(THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the Subscriber.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the buck springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the Novelty is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the Novelties, your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be apprised of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00), and we will also send to each new name a copy of the Premium Edition of the book, BEES AND HONEY. We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

yard seem no attraction for them. Indeed, I see them on nothing but the poppies, and they act as if they would devour every flower—roll and dive into the pollen like crazy things—but are shy of the many other flowers in the garden. Well, I don't complain. Guess they know their business. At all events they are multiplying and seemingly happy. I am wondering if they'll make me a nice lot of filled sections. No sign of it yet. DR. PEIRO.

Cook Co., Ill., July 6.

Bees Doing Well.

My bees are doing well on basswood and sweet clover. JOSHUA YOUNG.
Erie Co., N. Y., July 7.

Bees Had a Hard Time.

The bees have had a hard time of it—almost continuous rain. I had very little surplus from our two spring honey-plants—salmonberry and vinemaple—just enough to feed back now. I lost one colony out of 30, but have increased now to 35.

HERMAN AHLERS.

Clatsop Co., Oreg., July 3.

White Clover Fails to Yield.

You can put me down for blasted hopes as far as honey is concerned this year. Clover fails to yield, the pastures are white with it. Bees are just about holding their own. I am in hopes they will get enough to carry them thru till fall, as we generally get some honey from heart's-ease.

Henry Co., Ill., July 4. G. E. NELSON.

Keep Your Temper.

Be good-tempered. It pays in every way; it pays if you are an employer; it pays if you are an employee; it is profitable in every walk of life. And this is taking the most selfish view. You owe it to others to be good-tempered; you owe it to your own manhood, to your own self-respect. In making others comfortable, you are making things agreeable for yourself; you are gaining and keeping goodwill, which may be of value and help to you hereafter; you are accumulating a capital of popularity and good report which may be used to advantage, perhaps at a critical time. Good temper is a great factor in success.—Business.

The Midland Farmer

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 8.—Not any of the new comb from either than the Southern States has appeared on our market; most of that is amber to dark, and hence sells at an average of 80¢. New white that would grade choice to fancy would sell at 13¢; off grades of white, 11¢ to 12¢. Extracted, white, 70¢ to 75¢; ambers, 60¢ to 70¢. Beeswax, 20¢ to 27¢. R. A. BURNETT & CO.

KANSAS CITY, July 7.—A small shipment of new comb honey on the market is selling at 14¢ to 15¢. Good demand. C. C. CLEMONS & CO.

NEW YORK, June 9.—Demand good for extracted honey, all kinds, and same finds ready sale at the following prices: Fancy, 70¢ to 75¢; choice, 60¢ to 65¢; fair, 55¢ to 60¢; common, 50¢ to 55¢ per gallon. Some demand for comb honey at from 11¢ to 12¢ for white, and 9¢ to 10¢ for amber. No more demand for dark. Beeswax dull at from 25¢ to 27¢ per pound, according to quality. HILDRETH & SEGELKEN.

SAN FRANCISCO, July 5.—White comb, 10¢ to 10 1/2¢; amber, 7 1/2¢ to 9¢. Extracted, white, 7 1/2¢ to 7 3/4¢; light amber, 6 1/2¢ to 7¢. Beeswax, 20¢ to 27¢.

Market is firm at the quotations, with trading necessarily light, as only small quantities of new have so far arrived, and stocks of old are practically exhausted. It now looks as though this year's yield would not come up to the smallest estimates.

CLEVELAND, March 9.—Fancy white, 13¢ to 14¢; No. 1 white, 12¢ to 13¢; A No. 1 amber, 10¢ to 11¢; No. 2 amber, 9¢ to 10¢; buckwheat, 8¢. Extracted, white, 7¢; amber, 6¢; buckwheat, 5¢. A. B. WILLIAMS & CO.

BOSTON, May 17.—Fancy white, 12 1/2¢ to 13¢; A No. 1, 11¢ to 12¢; No. 1, 10¢; light amber, 9¢; buckwheat, 8¢. Extracted Florida, white, 7 1/2¢ to 8¢; light amber, 6 1/2¢ to 7¢. Beeswax, 27¢ to 28¢.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is liked at this season of the year. BLAKE, SCOTT & LEE.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11¢ to 12¢; some very poor selling at 6¢ to 7¢, and dull. No more business in honey before the opening of the ensuing season. BATTERSON & CO.

OMAHA, June 2.—A few little lots of new honey from Texas have made their appearance on the market. The stock was put up by inexperienced people and only sold at moderate prices. Extracted of fairly good flavor brought 55¢ to 60¢. Comb honey put up in 60-gallon cans and filled with extracted sold at 6 1/2¢. This is a most undesirable way of packing comb honey. Trade does not care for it. PEYCKE BROS.

DETROIT, July 15.—No old honey to quote, and no new offered. Prices are liable to rule higher as crop is short. The abundance of rain will no doubt help the crop of fall honey. Beeswax in good supply at 23¢ to 24¢. M. H. HUNT & SON.

TA RISE

To say to the readers of the BEE JOURNAL that **DOOLITTLE...** has concluded to sell **QUEENS** in their season during 1899, at the following prices:

- 1 Untested Queen \$1.00
- 6 Untested Queens 4.50
- 12 Untested Queens 8.00
- 1 Tested Queen 1.50
- 3 Tested Queens 3.50
- 1 select tested queen 2.00
- 3 " " Queens 4.00
- Select Tested Queen, previous season's rearing, \$3; Extra Selected, for breeding, the very

best, \$5.00. About a pound of Bees in a 2-frame Nucleus, with any Queen, \$2.00 extra. Circular free, giving full particulars regarding each class of Queens. Address,

G. M. DOOLITTLE,

11A26t Borodino, Onondaga Co., N. Y. Please mention Bee Journal when writing

22nd Year Dadant's Foundation. 22nd Year

Why does it sell so well?

Because it has always given better satisfaction than any other. Because in 22 years there have not been any complaints, but thousands of compliments.

We guarantee satisfaction.

What more can anybody do? **BEAUTY, PURITY, FIRMNESS, No SAGGING, No LOSS. PATENT WEED PROCESS SHEETING.**

Send name for our Catalog. Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

The following dealers handle our Foundation:

BEE-KEEPERS' SUPPLIES OF ALL KINDS.

Langstroth on the Honey-Bee, Revised. The Classic in Bee-Culture—Price, \$1.25, by mail.

Beeswax Wanted at all times.

CHAS. DADANT & SON,

Hamilton, Hancock Co., Ill.

Please mention Bee Journal when writing.

For Apiarian Supplies, address **LEAHY MFG CO.,** Higginsville, Mo. 1730 S. 13th St., Omaha, Neb. 404 Broadway, E. St. Louis, Ill. Please mention Bee Journal when writing.

Shipping-Cases, Cartons, Honey-Jars

We have several styles of Honey-Jars, among them the one-pound square Flint Jar, at \$4.50 a gross; 3 gross, \$4.30 a gross, and a discount on large orders.

Our Cartons are of a good quality of cardboard, much better than is usually sold for honey-boxes: \$4.50 a thousand; 5,000, \$3.80 a thousand. Sample free.

We carry in stock a full line of **APIARIAN GOODS.**

ITALIAN QUEENS: Untested, 50 cents each; 3, \$1.40; 6, \$2.60. Tested, 90 cents each. Catalog free.

I. J. STRINGHAM, 105 Park Place, New York, N. Y.

Please mention Bee Journal when writing.

24 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying **24 cents a pound—CASH**—upon its receipt. Now, if you want the money **PROMPTLY**, send us your Beeswax. Impure wax not taken at any price. Address as follows, very plainly,

BIOGRAPHICAL.

Three Generations of the Dadants.

BY THE EDITOR.

THE name of Chas. Dadant & Son is one too well known not only to all our readers, but to the whole world of bee-keepers, to need any words of introduction from us. However, it affords us considerable pleasure to be permitted

bee-business, in the earliest numbers of the American Bee Journal. He came to America in 1863, with the intention of growing grapes, but the grape-growing business proving a comparative failure, he again turned his attention to the bees. With the help of a dictionary and a weekly American newspaper he managed to master the English language, so as to be able to understand it and write it very fluently, but he has never been able to speak it freely and master the pronunciation, and his enunciation is difficult, so much so that those who meet him for the first time often wonder whether this can be the same man who wielded so ready a pen in the defense of the large hive, of which he has been the main champion.

Among Mr. Dadant's achievements in behalf of bee-culture are most prominent his successful importations of queens from Italy in 1874-75, and his revision of that classic in bee-culture—"Langstroth on the Honey-Bee"—which he

C. P. Dadant.

Louis C.

Maurice M.

Henry C.

Chas. Dadant.

to present on this page the pictures of a quintet of Dadants, and to give a little of their history.

Mr. Chas. Dadant was born in a village of Champagne, in France, May 22, 1817. He kept bees in France for pleasure when a boy, and long ago told of his adventures in the

republican in connection with his son in 1889, and of which a number of new editions have since been printed.

Altho Mr. Dadant is well known in this country, he is still better known in Europe as an extensive apiarist. His translation of the work of Langstroth, under the name of

"L'Abeille et la Ruche," which was also published in Russian, would have given him a leading place among European writers, if he had not already been known across the seas for his strenuous efforts during many years to extend the use of the movable-frame hive, and to fight the "routine" of the European peasants. How well success has crowned his efforts may be seen by perusing the bee-journals of France, Italy, Switzerland, Russia, and even of Spain, which also seems to be making an effort in the direction of progress. Even in the South American republics the echo of his voice has reverberated, and a step forward is being taken in the production of honey by progressive methods.

Altho Mr. Dadant is still the head of the well-known firm of Chas. Dadant & Son, he has practically retired from active life, but he keeps an eye on the current events of the bee-keeping world. His health is good in spite of his 82 years, yet he is annually compelled to leave home to avoid the hay-fever, to which he is subject during the months of August and September. He spends those two months every season in the pretty little town of Sturgeon Bay, Wis., in perfect immunity of this disagreeable disease.

Mr. C. P. Dadant, born in Langres, France, April 6, 1851, came to America with his father at the age of 12, and has resided in Illinois ever since. He is well known to our readers as one of our regular contributors, one of the directors of the United States Bee-Keepers' Association, and the manager of one of the most successful firms with whom our bee-keepers deal. Of his three sons, the eldest, Louis C., aged 20 years, is now a student of the Illinois State University, in the department of mechanical engineering. The second, Henry C., 17 years of age, has just graduated from the Keokuk high school, and is fitting himself for a business education. As to the third, Maurice M., he is yet too young to be able to say what he may be able to do; he has so far been trying his ability only in the rearing of Plymouth Rock chickens.

The Dadants manage six apiaries, comprising about 450 colonies, a large vineyard, and an extensive foundation-making shop. They produce extracted honey almost exclusively, and are among our most successful bee-keepers.

Several Delayed Questions and Their Answers.

BY G. M. DOOLITTLE.

SOME questions arrived along the latter part of the winter which the writer wisht answered thru the columns of the American Bee Journal, but in some way they got misplaced, so were not answered when they should have been. The writer of them is desirous that they be answered now, so that they may be in time for use when he wants to refer to them, and after hunting the matter up I have concluded to answer in July what would be more appropriate for December, altho it is generally best to answer questions, and give articles, which are appropriate for the time when they were written or appear in print.

LOCATING AN APIARY.

QUESTION.—Which is the better location for bees, one on low ground where it is moist and frosty in the spring, but sheltered, or one on high ground where it is more free from dampness and late frosts, but somewhat windy?

ANSWER.—If I could have my choice I would select neither. My choice would be midway on a moderate slope, say one inch to the foot, or such a matter, which faced toward the south, or more preferably the southeast. This would avoid the early spring frosts and the dampness of the low land, and, to a large extent, the high winds of the elevated position, which are almost sure to prevail. To be sure, a wind-break can be constructed around the apiary on the high ground, but according to my experience many bees are lost by being swept away on windy days upon rising above this enclosure into the cold blasts which blow above and about it, they being lured out by the calm and sunshine within. For this reason, were I limited to one of the two extremes, I would select the low ground in preference to the

high. If bees go out from the warmth caused by the mid-day sun shining on this low ground, they are not liable to be lost thereby; for when they rise high enough to strike the cold air from above, they at once fall into the warm air below, thus immediately warming again, so are not lost. Then, on the whole, the temperature at the low location will average much the warmer in early spring.

However, as I said at the start, if it were possible I should avoid the two extremes in locating, and take an intermediate one. But where our environments are fixt so that we cannot have our choice in such matters, happy is that man or woman who can make these environments the most nearly accord with what a good location would give us.

FEEDING BEES IN WINTER AND SPRING.

QUESTION.—What is the best method of feeding a colony of bees that is found to be without food in the hive in midwinter or early spring?

ANSWER.—In the first place, we should never allow our bees to be in this condition, for it is much more to our advantage, and to the advantage of the bees, to have sufficient food supplied them in the fall to last at least till the last month of spring, and I am quite positive that if enough is given to last till June it is all the better. The prudent apiarist will look over all his colonies in October, and see that *all* are abundantly supplied till the flowers bloom again. However, should such a thing as the bees being short of stores happen, thru sickness or other adverse circumstances, the very best method of feeding them is to set in combs of sealed honey, as this places the bees in a natural condition, and does not disturb them every little while, as most other methods of feeding do. If no combs of honey can be had, the next best way is to fill combs with good, thick sugar syrup, when they are to be used the same way the combs of sealed honey would be. In either case, such combs of feed should be warmed for six hours or more before being placed in the hives, for where combs of frozen honey are set next to the bees the colony is thrown into a state of excitement to warm this honey up to where they can safely cluster against it.

There is still another way of feeding in winter which I like very well, and can be used still more effectively in the spring where a colony is short of stores, where one has on hand some extracted honey which has candied, which is as follows:

Make a bag out of cheese-cloth about six or eight inches square, after which partially fill it with the candied honey, which has previously been workt till it is quite soft, or it can be workt after it is in the bag. Don't fill the bag so but that it will assume a flat shape, for we wish to press it down right over the cluster of bees, so that it can be covered snugly with bee-quilts or old carpeting to keep in the heat. The bees will suck the feed thru, and in process of time cut thru the cloth so as to use it all up.

But let me repeat, that the bee-keeper who does not see that each colony has stores enough in the fall to last from October to May, is working in such a way that the word "failure" is liable sooner or later to be inscribed on his banner.

FALL AND SPRING WEIGHT OF COLONIES.

QUESTION.—What becomes of the difference between fall and spring weight of colonies, sometimes amounting to from 20 to 25 pounds?

ANSWER.—Bees use honey largely as fuel during the winter season, in order that they may not freeze during the frigid weather of our northern localities. I reason like this:

The natural food of the honey-bee contains the least possible amount of gross matter, and as bees do not take on fat and thereby increase in weight, the digestion of honey in the stomach of the bee is equivalent to combustion, or, in other words, the honey is burned up, hence as the ashes of burned fuel do not weigh anywhere near as much as the fuel did before burning, so the "ashes," or what is left in the intestines of the bees, weigh much less than did the honey consumed to keep up the fire.

Again, much of the weight goes out by evaporation; and should the bees have a flight, more would go out by way of excrement, but not nearly as much by the latter as by the former. Honey being very free from nitrogenous matter, it is past off in liquid or vaporous form by way of sensible and insensible perspiration and respiration, except the small amount to be found in the bodies of the bees. This is sometimes carried on to such an extent that water is seen running out at the entrance of hives in winter. Some of the food is also used in producing muscular force, and as this force is constantly wearing out, the loss is per-

ceptible in the food, while in the weight of the bees it is not seen.

In all of the above we see the wisdom of Him who created the bees, for were it otherwise they could not stand the rigors of our Northern latitudes at all, inasmuch as they are too clean to soil their hives, while the weather will not admit of their leaving them, often for months in succession. Onondaga Co., N. Y.

Queen-Breeders Defended—Judging from the Progeny of a Queen.

BY J. M. DONALDSON.

HASTY judgment is a failing that mankind is more or less heir to, and bee-keepers not being exempt, the queen-breeders, like the supply and commission men, are often the victims. Sometimes it may be deserved, but I will venture to guess that nine times out of ten it is entirely uncalled for.

I do not put forward the claim that all queen-breeders are strictly honest. We have good and bad in almost any calling. No doubt there are a few men who rear queens for market that are careless and slipshod in their methods, their only aim being the accumulation of the almighty dollar; but of this I am not qualified to speak.

We have a class of queen-breeders who are careful and considerate—men who have devoted the best days of their lives to the study of the honey-bee, its habits, and the best methods for rearing queens. Such men are not only a credit but a benefit to the bee-keeping fraternity, because they are doing what the rank and file of bee-keepers have neither the time nor the patience to accomplish, namely, improving the present race of honey-bees by breeding out the poor qualities and breeding in the good ones. Men of this class could not afford to injure their reputation by misrepresenting their stock or by sending out poor queens. I do not think they would knowingly do so, still I have received queens from this very class of men that fell far short of my expectations, as far as egg-laying was concerned; but I do not think the one I bought them from was trying to swindle me.

I am thoroly convinced that a queen that has been very prolific while in the yard of the breeder may, after making a journey in the mails, turn out almost useless as an egg-layer. I never studied entomology, and cannot explain why this should be, but I will relate an experience I had, on which I base my opinion:

Three years ago I wanted to improve my stock, so I sent an order for a select-tested queen of the previous season's rearing. This order was placed with one of the best-known breeders. The queen arrived and was safely introduced. As this was the highest priced queen I had ever owned, I was much interested, and kept a close watch of her. I was somewhat disappointed when I found she was not keeping up the strength of the colony. But there were other things I noticed, which saved me from the common error of writing a saucy letter to the man from whom I bought her. Her progeny was as handsome as any bees I had ever seen, and in proportion to the number the hive contained they were the best hustlers in my yard. They were the first out in the morning and the last in at night. I concluded to try breeding from her before making any complaints; the result was as good queens as it had ever been my pleasure to own.

That season a friend of mine (who is also a bee-keeper) made me a visit. He took quite a fancy to my nice, yellow bees, and askt me if I would send him a queen. I pickt out one of the very best I owned, and sent her to him. Last summer my friend paid me another visit; of course I askt him how he liked the queen I sent him. Imagine my surprise when he told me that if he were buying them, he would not pay one dollar a dozen for queens such as she was.

From the above facts I came to the conclusion that when buying queens, should they not quite meet my expectations, I would always breed from them and see how their queen progeny turned out before I entered my complaints to the queen-breeder. Worcester Co., Mass.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

Foul Brood Germs—Difference Between Spores and Bacilli.

BY THOS. WM. COWAN.

SINCE I wrote to you on this subject I have received gleanings in Bee-Culture for April 15, and in it I find two letters in reference to which I should like to make a few remarks. Mr. Harry S. Howe, writing with regard to the several boilings in order to secure the sterilization of honey, points out that "the spores of *Bacillus alvei* do not develop in honey, nor can they live in honey except in the spore condition." I would agree with this entirely if it were restricted to honey in a normal condition. But it would indeed be a bold person who would venture to say that honey is always in this state, and that it cannot be in such an abnormal condition as to form a suitable medium for the germination of spores of bacilli. We know the living spores remain dormant, and bacilli cannot grow in honey, because in a normal condition it has an acid reaction; but should it, from any cause, become even slightly alkaline, there would then—if other conditions obtained—be no hindrance to their germination and development. It was with a view to the possibility of such a condition that I wrote advisedly in my last letter respecting several boilings of honey—"supposing a nutrient medium to exist in the honey, the unaffected spores would germinate into bacilli, and could be destroyed in the next boiling."

On page 310, there is "A new treatment of foul brood" by our old friend Rambler, and a recommendation to uncap a comb affected with foul brood, and wash it under a faucet of water running with considerable force. I should like to point out the great danger of this plan. The combs that are uncapped contain thousands of spores; and in washing many of these would be driven out of the cells and spread by the running water, we know not where; and as they are not destroyed they are at any time ready to restart the mischief. When the combs are in this condition it is always safer to burn them, as we thus destroy all the spores.

Then as to formalin, I do not think it would have any more effect upon the spores than any of the other drugs have, altho it may be equally efficient in destroying bacilli. It seems to me that, in many cases, the non-success of drugs has been owing to not properly understanding the great difference between spores and bacilli.

Now, in any inquiry into the influence of one drug or another on micro-organisms, it is necessary to bear in mind that the influence of certain conditions on the micro-organism may be a twofold one. First, the condition may be unfavorable to the growth of the organism; and, second, the condition may be fatal to the life and existence of it. The second condition involves, *a fortiori*, the first; but the reverse is not the case. A great deal of confusion has arisen on this subject, owing to the failure to distinguish between these two propositions. We constantly hear of this or that substance being an "antiseptic," which means that it is inimical to the growth of micro-organisms, or that it is a "germicide," meaning that it kills the organisms. The scientific man, of course, knows and understands the difference between the two; but the great bulk of people do not, therefore they expect drugs to perform impossibilities.

I see Rambler calls formalin an antiseptic, therefore it is probable that it will prevent the growth of spores only while in contact with it, or kill the bacilli. This is precisely the behavior of all the other drugs used, and they can do no more. Spores are invested by a thick, double membrane; the external sheath is supposed to be cellulose, and the internal one probably of a fatty nature, both being bad conductors of heat. It is this double membrane that gives spores this great resistance of high and low temperatures to acids and other substances. I do not think any amount of soaking in water would render the spores open to the influence of diluted formalin. Now, we know there are many antiseptics, and these can be used effectually against foul brood. Carbolic acid, phenol, thymol, salicylic acid, naphthol beta, perchloride of mercury, and many other substances, even when considerably diluted, prevent the growth of bacilli.

Now we have had considerable success in England in our treatment of foul brood, which involves the use of drugs. We call this an antiseptic treatment, because it is the same in principle as the antiseptic treatment in surgery, which has made it possible to perform with success the marvelous operations of the present day, and such as could not have been effected without almost certain loss of life from blood-poisoning induced by the growth of various micro-organisms. We insist on an antiseptic always being present in the hive or in the food we give to our bees. No

syrup or honey is given without first being medicated, and the antiseptic used kills any bacillus that may be growing, or prevents the spore from germinating, altho it does not kill it.

Then we know that there are certain chemical substances which evaporate at the ordinary temperature of the hive, and whose vapors prevent the growth of bacilli, altho they do not destroy them. Among these are eucalyptus, carbolic acid, phenyle (or creolin), lysol, camphor, naphthalene, and others. For convenience and economy we use naphthalene, and have some of this always present in the hive. Our treatment is this:

If we detect the disease in its earliest stage, before any of the affected larvae are capt over, we simply feed the bees with syrup medicated with naphthol beta, because at this stage there are no spores present. The medicated syrup is used by the nurse-bees in preparing food for the larvae, and in this way the bacilli are destroyed. It is, however, seldom that the bee-keeper is sufficiently expert or alert to detect the disease at this stage, but more generally notices it only when the combs have irregular patches of brood, with sunken and perforated cappings to the cells containing the coffee-colored mass inside. In this condition the cells are crowded with innumerable spores, and the treatment just mentioned would not have the slightest effect upon them. If the colony be weak we destroy the bees, combs, and quilts, and disinfect the hives. We thus destroy the spores, and so remove the source of infection.

Should the colony be strong in bees we make an artificial swarm of them, confine them in an empty hive, and feed on syrup medicated with naphthol beta. We use this drug because it is non-poisonous or corrosive, and has no odor repugnant to the bees, is a powerful antiseptic, and can be used in great dilution, thus rendering it economical. The frames, combs and quilts are then burned, and the hives disinfected by being either steamed or scrubbed with boiling water and soap, and then painted over with a strong carbolic-acid solution. The bees are confined in the empty hive for 48 hours, by which time all the honey they may have taken with them will be consumed, and such of the bees as are diseased will have died off. Those remaining are then put into a clean hive furnished with full sheets of comb foundation, and are fed with medicated syrup for a few days longer.

With this treatment, when faithfully carried out, we have had considerable and very gratifying success. The whole secret of this success lies in having the drug ever present to act on the micro-organism, and either kill it or prevent its development and growth. I do not see why formalin, if used in the same way, should not be as efficacious.

[Editor Root then follows with this foot-note:—EDITOR.]

I am sure we bee-keepers of the United States are exceedingly obliged to Mr. Cowan for the valuable information he has given us, and for the clear way in which he has discriminated between spores and bacilli.

As I understand him, the purpose of medicating syrup fed to bees is to kill the spores immediately on their entrance to the bacillus form, as well as the bacilli themselves. Drugs can in no sense kill spores; but if the syrup is medicated with the proper antiseptics, when the spores do hatch (if I may adopt an unscientific term) the microscopic life is killed at once.

This naphthol beta is something that I believe American bee-keepers can use with profit, especially those who have had foul brood in their vicinity, or at least who have had it in years gone by, and are troubled with its reappearance occasionally. If every year all the syrup fed to the bees in such apiaries is medicated with naphthol beta, the time will come when the last traces of the disease, even in spore form, will be wiped out.—Gleanings in Bee-Culture.

The Need of Taking Bee-Papers—An Apiarian Sermon.

BY REV. L. J. TEMPLIN.

WE are living in an age and a country of intense physical and mental activity. Discoveries and inventions crowd on each other with a rapidity that is bewildering. A few centuries ago a man might possess all kinds of knowledge, but to-day to be fairly informed in one or two branches is about as much as a man can successfully aspire to, and to be an expert in any one field of knowledge will tax any man's faculties and energies to their utmost. The

discoveries and advances made in any one branch of human knowledge follow each other with such rapidity, the old giving way to the new at such frequent intervals, that even the expert has to hustle to keep up with the advancement of his own specialty. The need of fresh information along all the different lines of knowledge and activity has led to the publication of journals devoted to each of those fields of activity. The man who fails to take and read one or more of these publications devoted to his branch of business, will soon find himself like a chunk of driftwood lodged on the bank of the stream after the flood has gone by.

While this is true of all branches of knowledge and industry, it is eminently so of bee-keeping. Scientific bee-culture is less than 50 years old, and it would be sheer egotism for us to claim that we have attained to anywhere near perfection in the pursuit. We do well to revere the memories and honor the names of Langstroth, Quinby, Grimm, and other fathers in bee-keeping; and we will profit by a thoro study of their excellent works on the subject; but we do not want to sit down on their graves, and dream that all has been accomplished that is attainable. For in that case the world will soon move on and leave us behind; for as Galileo declared, after recanting his teachings in regard to the motion of the earth around the sun, as he rose from his knees before the dignitaries of the church he remarkt in their hearing: "It does move, tho." And so the man who sits down and waits will find, Bro. Jasper to the contrary notwithstanding. Such a man has made a mistake; he ought to have been born two or three centuries earlier.

By the way, what an age and a country we are living in. Standing on the verge of the closing century, and looking backwards across the years we see, with the exception of the one all important event in human history, the incarnation of the Son of God for the redemption of men, the most important of all the sixty centuries covered by human history. A list of the mechanical inventions and the discoveries in science that have been made during the present century would more than fill a full number of the American Bee Journal. Going back to near the beginning of the century we find in 1807 Robert Fulton launching his first steamboat on the Hudson River. This drove the many boats propelled by oars to the shore to rot.

Next came the railroad, superseding the freight-wagon and the prairie-schooner wherever it went. Then came the telegraph annihilating time and distance; and now the telephone threatens to annihilate the telegraph. Near the middle of the century the steamship put in an appearance in spite of the assertions of scientific men that it could not succeed. These great floating palaces, which are almost like floating cities, have replaced the old sailing-vessels, reducing the time of passage from several months to less than a week. A very learned man in England wrote a very learned pamphlet to prove that in the very nature of the case it was impossible for a steamship to cross the Atlantic Ocean. The first copy of that pamphlet that was ever brought to America was brought over in a steamship.

The old wooden war-vessels have given place to the great steel-built and steel-armored war-ships with guns that will hurl shot and shell a dozen miles, and with such accuracy that a ball can be planted inside of a square yard at the distance of two or three miles. In small arms the repeating rifle and the Maxim rapid-fire guns have displaced the old smooth-bore and muzzle-loading arms of past years.

The mowing and reaping machines have superseded the old sickle, cradle and scythe. The separator has done away with threshing with the flail, and the tramping of horse and oxen. The sewing-machine, with its tick, tick, tick, has rendered obsolete the "Stitch, stitch, stitch, band and gusset and seam," of Hood's needle-woman. The old hand printing-press, workt with so much back-breaking energy, has given away to the great Hoe power press that will print and fold thousands of the great daily sheets in an hour, to be scattered over all the country, like leaves of the forest, carrying more light and knowledge, more slander and degradation, than any other agency ever employed by the race.

The electric light has caused the candle, the kerosene lamp, and even the gas jet, to largely pale into dimness; and as a motive force electricity threatens the dominion of steam itself. Sir William Thompson, probably the highest authority in the world, recently said: "The steam-engine is passing away." And in liquified air may be concealed latent forces that will render even gunpowder and electricity back numbers.

All these, and a thousand other wonders, have been achieved within the life-term of people yet living. The writer, tho a good many years short of three score and ten,

has seen three dozen men in a field at the same time wielding the old sickle or reap-hook, keeping step and moving together with the precision of well-drilled soldiers. He has seen grain threshed with a flail and winnowed with a sheet. He remembers when the women cooked by the fire-place in pots and kettles, and when the cook-stove was introduced amidst the usual opposition to new things. The spinning-jenny and power-loom have turned the hand-loom into stovewood, and relegated the old spinning-wheel to the garret, whence it is brought on "state occasions," as relics of a bygone age. The writer has seen hundreds of pounds of wool and flax spun and woven, in his own home, on these now superseded implements.

No man can say what the future has in store for us, and no wise man will venture to predict that anything that anybody wants done will not be done. It is a grand time to live, with the bright past and brilliant future. I cannot understand how anybody can sit down on an old bee-hive and sulk or think of discouragement. The supply of earnest, energetic, courageous people, is far below the demand. Especially to the young, the times appeal for pure, healthy bodies, thoroly cultivated minds, and large, sympathetic hearts, to grapple with the great problems of life, and lift

L. J. Templin.

till they see stars, and even far beyond them, to aid in elevating the race to a higher plane of life.

To succeed in the bee-business, or any other for that matter, one must be alive. And life means more than mere existence. Nothing has a more real existence than a granite boulder, and yet we never think of it as possessing life. Life means correspondence with one's environment. This correspondence is not duration, but knowledge. The nature of this life depends upon the character of the environment with which one corresponds. If the environment is limited the life is limited; if it is temporary the life is temporary, and if the environment is eternal the life is eternal. "This is life eternal to know Thee, the true God, and Jesus Christ whom Thou hast sent." Knowledge is life. This correspondence with, or knowledge of, God constitutes eternal life. It includes the idea of unending existence, but means much more than this. This life begins here, and now, whenever a soul comes into this sympathetic correspondence with the eternal environment, and is extended into a future state of existence. Death has no more power to begin or end this life than a light frost has to begin or end the life of a pine tree.

So the life of the bee-business consists in a knowledge of the bee-hive with all its appurtenances, that will stimulate the individual to put forth his or her best efforts to produce the best possible results. As one cannot understand

about eternal life without studying His Word, neither can a bee-keeper keep up with the constant advance in knowledge and methods of his business without studying what has been done and written, and what is now being done and written by the masters in the business. In order to do this he must not only read the standard books on the subject, but he must take and read one or more of the excellent publications now furnished so cheaply. The man who thinks he does not need these helps will soon find himself trotting along behind the band-wagon, when the main procession has moved on out of sight. The world has no use for an old foggy. Society has enough inertia of its own, without hitching on a lot of dead men, or those who ought to be dead, to clog the wheels of progress.

It seems a part of human nature for men to become conservative as they grow old. Standing with their faces to the past, as the young do with theirs to the future, they gradually fall out of sympathy with the present. We sometimes hear them lamenting for the good old times. Take away from them all the inventions and discoveries, all the blessings and good influences that have come to the world in the last 50 years, and a few weeks' experience would satisfy them with "the good old times." I have often thought what an excellent scheme it is, that when a man loses interest in the world and its advancement; when he becomes fossilized, and a shell forms on him that will no longer expand in sympathy with a moving world, that death comes along and quietly lays him in the grave where he will no longer be disturbed by the changes and innovations of a younger generation.

Did it ever occur to you what a condition the world would be in if the generations that have lived and died in the past were living, with all their prejudices, fogginess and narrowness? What a time we would have in making any advance or improvement along any lines of human interest. Propose any improvement or change, and you would be met with the response: "Why, that is not the way we did two thousand years ago." Another would be ready to declare that five thousand years ago such a thing was never thought of. Would we not have a fearful task in heaving the world up such a hill as that? Why, it is bad enough as it is, when one man in ten thousand does not live to be a hundred years old. No man has a right to stand in the way of the real progress of the world; so if Dr. Miller, or Root, or Doolittle, should become fossilized or ossified in the joints of their minds so they cannot dismount from some hobby that has become crippled or so antiquated that it cannot keep up with the movements of the bee-keeping world, let him retire, and let the boys come forward and run the ranch awhile.

The bee-business is a delightful one—if we can only succeed. But while enjoying the sweets of this life it is well to remember that which is "more precious than gold, yea than much fine gold, sweeter also than honey and the honey-comb."

Well, I could wish that all bee-keepers might live to be a hundred years old (if they would not get foggyish), and then be translated to a happier clime, where the ills of this life are not known.
Fremont Co., Colo.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 50 cents; 50 for 70 cents; 100 for \$1.25; 250 for \$2.75; 500 for \$4.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

The Premiums offered on page 474 are well worth working for. Look at them.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Blacks and Italians in the Same Hive.

I Italianized a colony of black bees in October, 1898, and I thought they were all right, but when I examined them the past spring I found about $\frac{2}{3}$ of them were pure Italians, and $\frac{1}{3}$ pure blacks. There is not a hybrid in the hive. I have been keeping bees for 15 years, and I have never seen anything like it before. VIRGINIA.

ANSWER.—The first cross between blacks and Italians are by no means a uniform lot, but part of them are in appearance Italians and part are black. So what you have observed is the rule and not the exception for the first cross. With later crosses the appearance of the workers becomes more uniform, showing one or two bands on each bee.

Transferring Bees from Box-Hives.

How can I transfer bees from box-hives into new frame hives? The combs in the old box-hives seem to be in every shape and form. WISCONSIN.

ANSWER.—How to transfer has been asked for several times in the past few months, and in each case it was replied that the text-book should be consulted, for this department is merely intended to supplement the text-book without going over all the ground contained therein. It may be said, however, that you may do better not to transfer now but to leave the bees where they are till time of fruit-bloom next year. With combs "in every shape and form" in the box-hive, it may not be very satisfactory to try to fasten them in the frames of the new hive. Perhaps the better way will be to leave the bees in the box-hive till they swarm, hive the swarm in the new hive, then 21 days later all the worker-brood will have emerged, and the old hive can be knocked to pieces.

Mating and Laying of Queens—Ants in the Hive.

How long should it be after a queen emerges before she begins laying? Prof. Cook says six or seven days. In my experience it is much longer. On May 5 I had two queens out in a queenless hive, and I put one of them into another hive, also queenless. I looked several times but it was not till June 16 that I found any brood in either colony, and then only a small portion was sealed.

Again, two queens emerged in two nuclei, one a two-frame observation hive, on June 16, and to-day (July 2) there is no brood nor eggs. On June 30 I saw the queen fly out from the observation hive three times in the course of an hour, twice returning in about 5 minutes, the third time in about 30 minutes, without any sign of having met the drone. On July 1 she again went out three times, remaining out as before: the last time I think she met a drone as the vulva was open, but no appendages were attached.

Were the above periods longer than usual? If so, what do you suppose was the cause? There were plenty of drones flying: during May and early June the weather was mostly cool and wet. I was much troubled by some very small ants getting into the hives. I got rid of them by putting some poison fly-paper into a small tin box, wetting it with honey, or sugar and water, and covering with fly-wire to keep the bees from getting at it. The ants were soon crowding into it, but the next day there was not one to be seen.

BRITISH COLUMBIA.

ANSWER.—Prof. Cook says in his Manual, "Five or six days after issuing from the cell—Neighbour says the third day—if the day is pleasant the queen goes forth on her

"marriage flight; otherwise she will improve the first pleasant day thereafter for this purpose." Again he says, "About two days after she is impregnated, the queen, under normal circumstances, commences to lay." That, you see, would make the queen seven or eight days old at time of beginning to lay. But he also says, "If the queen fails to find an admirer the first day, she will go forth again and again till she succeeds. Huber states that after 21 days the case is hopeless." That's as much as to say that she may not be fertilized till nearly three weeks old.

You notice that Prof. Cook says, "under normal circumstances." Queens reared under normal circumstances are in full colonies and the harvest and other circumstances are favorable. The case may be very different if a queen is reared in a nucleus, or if the weather is unfavorable, or if there is a dearth of pasturage. If a queen is reared in a nucleus, even if the cell from which she issued was sealed in a full colony, you will probably find it much oftener that she will begin laying at 12 than at 8 days of age. If her whole larval life was spent in the nucleus, the case is still more unfavorable, and more and more in proportion to the weakness of the nucleus. With bad weather such as you had, you will probably always get about the same results as you had with nuclei. The queen that emerged May 5 and had sealed brood June 16 could not have been more than 34 days old, and she may have been considerably younger. For at first she probably laid very few eggs in a day, and part of the few sealed cells may have been sealed several days. There may have been delay in fertilization, and delay in laying. In the queen hatch in the observation hive you have a plain case of fertilization after two weeks old, and you need not be surprised if that queen commences laying much later than two days after fertilization.

The ants probably did no harm to the bees, but they are annoying to the bee-keeper, and you took a good way to settle them.

Bees "Wrong End Up" in the Cells—Drone-Laying Queen.

1. I have one colony that is dwindling. They have lots of brood and it looks healthy. I uncapt a lot of brood and about half of it was turned the wrong end up. The larva look nice and healthy and were alive, but of course they could not gnaw out of their cells. What is the matter, and what shall I do about it?

2. I put hive-bodies full of combs under strong colonies last spring, and the queen went down and laid drone-eggs in worker-cells, filling two to three frames of drone-brood. The workers lengthened the cells and they (the capt cells) look like big warts. Is that regular when you give room below, or is it a freak? WISCONSIN.

ANSWERS.—1. I don't know. It is a very unusual thing to find bees "wrong end up" in the cells, and some have ventured the suggestion that it resulted from weakness. You say the "larva" was wrong end up. If you mean really "larva," it would be an easy thing to be mistaken as to its position, for each end looks like a tail. But if you mean pupa, that is after the form of the head can be plainly seen, then the case is a very unusual one, and I know of no remedy except to give the bees all the chance you can to be strong in numbers, and possibly that may make no difference.

2. The combs being in the under story had nothing to do with the case. It was a case of a drone-laying queen, and you will find that when the queen went up-stairs she did the same work there.

Sand-Vetch—Web Attach to Bees.

1. Is sand-vetch a honey-plant? My bees work on it all the time.

2. Why do some of the young bees come out with a white web attach to them so that it is difficult for them to fly? What is the remedy? ALSTAD.

ANSWER.—1. It must be a pretty good honey-plant (I've had no experience with it) or else the bees wouldn't work on it all the time. At least it must be one of the best yielding at the time. For a plant that yields rather poorly will be well visited by the bees when nothing better is to be had, but will be deserted as soon as something better offers.

2. Possibly it is part of the web of the wax-worm. The remedy is to keep strong colonies, and especially Italians. A very weak colony of Italians will keep out the moths.

Bees in the Walls of a House.—A colony of bees were located in the dead-air space between the two walls of a brick house. A. D. Hopps threw in carbolized water all thru the sides by means of a small syringe, and that being more than the bees could stand they came out and were hived. *Gleanings in Bee-Culture.*

Duties of Worker-Bees are thus given by A. H. Duff in a Kansas Bulletin: At two or three days old, preparing food and feeding larvæ; at 10 or 12 days old, secreting wax and building comb; at about 20 days old, field-work. The generally accepted age for field-work is 16 days. It would be interesting to know upon what grounds Mr. Duff has departed from the traditions of the fathers.

Controlled Fertilization of Queens.—Dr. Mason gives further publicity in the Bee-Keepers' Review to an item given in Canadian Bee Journal. The Doctor had tried shutting in at 9 a.m. virgin queens and the drones he wanted to meet them, then letting them out when drones had ceased to fly, but both queens and drones were uneasy, fretting and stewing to get out for a flight. Mr. Holmberg has supplied the missing link by putting the nuclei in the cellar where they keep quiet, giving the nuclei a good supply of drones.

Wax-Moths in Strong Colonies.—Dr. Bartrum demurs to the statement of British Bee Journal that there is little fear of wax-moths in strong colonies. Even with the strongest colonies he finds it "advisable to squeeze putty" into all the crevices on the top frames of the combs, "in order to avoid injury to surplus honey. Possibly the kind of bees has something to do with the case. In England black bees are preferred by many to Italians, and it is well known that blacks—in this country at least—will not protect themselves against moths as will the Italians.

Capacity for Strong Colonies.—A. H. Duff says in the Kansas Bulletin that it would be a fatal mistake to confine a very strong colony to a single story of usual dimensions. A second story should be added, the bees using both stories for brood and honey combined until the beginning of the honey harvest. Then only one of the stories should be left, if comb honey is to be produced, this story being filled with brood. In place of the removed story, two tiers of sections should be given above. If the extractor is to be used, leave both stories, putting the brood below and the honey above.

Separator and Non-Separator Honey.—A picture is given in *Gleanings in Bee-Culture* of eight sections of extra-fancy honey in bee-way sections. The honey is snow-white and of fine flavor, the only drawback being that some sections are too full and some are lean because separators were used only in every alternate space. Editor Root thinks more honey could be obtained for such honey by using the full number of separators. It seems that some make a success of producing section honey with half the usual number of separators, or with none at all, but in some circumstances, perhaps in most circumstances, it is wisdom to use them.

Do Bees Made Queenless Choose Larvæ too Old for Good Queens?—Some time ago Dr. Miller took issue against the somewhat generally accepted theory that bees left to themselves, in their haste to secure a queen as soon as possible, would select by preference larvæ so old that good queens could not be produced from them, maintaining that a queenless colony when left to itself would select the best material it had on hand. Several of the leading writers stood up for the old theory, declaring that actual experiment had shown that when a queen was suddenly removed from a colony a lot of very poor queens was reared. In *Gleanings in Bee Culture* Dr. Miller says beliefs have been read into his article that he never held. He thinks it the instinct of the bee to rear a number of queens, not all at the same time but somewhat in succession, and after the first few days of queenlessness there being no sufficiently young larvæ present the bees will use those too far advanced, and these will produce poor queens. If all the queen-cells are

used the result will be bad. But if the matter is left entirely to the bees to secure from the lot only one queen, the queens first started from the young larvæ will mature before the objectionable ones, and the result will be a good queen. Also if several of the cells are given to a nucleus, the chances are in favor of a good queen. But he counts that the Doolittle plan has the market advantage that all cells may be good.

Prevention of Swarming by Perforated Zinc at Entrance seems to be one of the things at which the novice quite generally grasps with alacrity. As a swarm cannot go off without a queen, it seems the natural thing for the inexperienced to jump at the conclusion that a measure that will prevent the departure of the queen will prevent swarming, without taking into account the fatality that may accompany such a thing. To the inquiry of one more who has conceived the idea of preventing swarming by means of perforated zinc at the entrance, the editor of the British Bee Journal replies with perhaps a shade of impatience (an impatience which is quite justified) that the idea of preventing swarming by such means is absurd. The thing has been tried again and again, and only failures reported. Among other troubles, "excluders have become blocked by drones endeavoring to squeeze thru in the headlong onrush of a swarm, and strong colonies half suffocated thereby in hot weather."

Management for Comb Honey.—H. H. Hyde, having said that as soon as the fast flow has commenced he goes thru, filling the bottom story full of sealed brood as much as possible, placing frames of the youngest brood at the outside of the hives, S. P. Culley heartily endorses the plan, and says: "The principles involved, are briefly, it secures the right conditions to insure prompt starting and vigorous work in the sections, to-wit: (a) it gives a brood-chamber full of brood, not much honey; (b) it obviates the necessity of bees traveling over much honey to reach the super—a thing four out of five colonies do with extreme and expensive reluctance and one or more out of five refuse to do at all; (c) it invites the bees to store honey directly over the brood, which is in harmony with their own idea; (d) placing 'frames of the youngest brood at the outside' of the brood-nest diverts from storing at the sides of the brood to storing above, in the sections." *Progressive Bee-Keeper.*

Queen-Excluders Indispensable for Extracting, altho not necessary for comb honey, is the theme of C. A. Hatch in *Gleanings in Bee-Culture*. He says that without excluders more combs must be used for the same amount of honey, as much of the storage-room is occupied with brood and pollen; labor is saved in the fall, for with the excluder the brood is all where it ought to be; but the strongest point he makes—a point that can hardly be emphasized too strongly—is that without the excluder the queen will occupy extracting-combs, and the food of the larvæ will be thrown out in the honey, to say nothing about the larvæ themselves floating around in it, and the lowering in this way the quality of the honey is a very serious matter. He believes in using plain sheets of perforated zinc. These should not be given when the super is first put on, but after the bees are well started, even if the queen lays in the super. When the excluder is given, put queen and brood below, or at least put only sealed brood above.

Rearing Queens by Unqueening a Colony.—The editor of the Bee-Keepers' Review refers to an article in *Gleanings in Bee-Culture* in which Dr. Miller admits that when left to their own choice some of the queens will be poor, and holds the Doctor still in error in insisting that the first queens hatch will be good, and that bees continue to start queen-cells after larvæ are too old. Even if the first queen is best, *sometimes* she goes off with a swarm. Mr. Hutchinson has started as many as a thousand batches of queen-cells, and till he knew better followed the plan of making a colony queenless. Most of the cells were started the first day after the queen's removal—occasionally one the second day. All hatch on the same day, with an occasional one a day later. That is, the regular cells, but sometimes two or three days after the regular batch was started, what he calls "fool-cells" were started with half-grown worker larvæ, producing worthless queens. So his bees don't do as the Doctor claims—continue starting cells in succession. As Dr. Miller seems to stand alone in his views, one might be excused for asking him why, since he is not a queen-breeder, he should pit his limited observation against that of all those who have reared queens by the thousand.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,
15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39.

JULY 27, 1899.

NO. 30

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Cuba as a Honey-Country has been much discusst of late. Aaron Snyder has his say in the Bee-Keepers' Review. It is the best honey-country in the world, but after an actual trial he finds so many drawbacks that he does not care for any more of it. Any one thinking of taking his family there should first go himself for six months or a year, and Mr. Snyder says: "It is my opinion that there will not be one man in ten who will not wish, at the end of six months, that he had left *himself* at home."

Shipping Beeswax.—Early this year we had something to say about shipping beeswax in sacks instead of boxes, in order to save freight. It seems that it may not have been good advice, if Mr. G. K. Hubbard is correct in the following, which we received last week:

EDITOR YORK: I have for some time been wanting to call your attention to an error you made in your paper of Jan. 7, in advising how to ship beeswax; but as the Dadants have given the same advice privately, when to follow it would have certainly resulted in a loss to the shipper, you will see you have good company.

You think it wise to ship from distant points in sacks to save weight. Being saving in the weight of the tare is always advisable, when that is the only point to consider, but in the case of beeswax and many other articles, where the classification list provides for a certain rate if shipped in boxes or barrels, there is also a provision that such articles, if shipped in sacks shall take a rate *50 percent higher*. To il-

lustrate: 176 pounds of beeswax shipped to you from Riverside, Calif., in a 24-pound box or barrel, making 200 pounds gross, would cost, at the present rate of \$2.25 per 100 pounds, \$4.50. But if the wax was shipped in sacks weighing four pounds, making the shipment 180 pounds gross, the freight charges would amount to \$6.07, because when so packed it requires a rate of \$3.37½ per 100 pounds.

G. K. HUBBARD.

We must confess that we were not aware that there was any such difference in classification as Mr. Hubbard mentions, and see no good excuse for it. Certainly, beeswax ships just as safely in sacks as in anything else, and just why the railroad companies should make a higher rate when thus shipped than when in boxes, we cannot understand. Evidently that classification needs revising.

The Philadelphia Convention Program.—Dr. A. B.

Mason, Sta. B, Toledo, Ohio, the secretary of the United States Bee-Keepers' Association, has sent us the completed program for the national convention to be held in Philadelphia Sept. 5, 6 and 7, next. A copy of the same follows:

Necessity of Pure Food Legislation from a Bee-Keepers' Point of View—Rev. E. T. Abbott.

Out-Apiaries and their Management for Comb Honey—W. L. Coggsball.

Possibilities and Difficulties of Bee-Keeping in Cuba and Porto Rico, and the Effect of Our New Relations With those Islands on Our Honey Market—Fred L. Craycraft and W. W. Somerford.

Best Method of Comb-Honey Production, with Latest Hive Improvements—F. Danzenbaker.

The Fall Honey Crop of Philadelphia—John L. Kugler.

Organization Among Bee-Keepers: If Desirable, Why, and How Best Accomplished?—Thomas G. Newman.

Best Method of Extracted Honey Production—Frank Ranchfuss.

Address by A. I. Root.

Pads, Fancies and Follies in the Apicultural World—Hon. Eugene Secor.

The Products of the Bee—Pollen, Propolis and Honey—W. A. Selser.

Food Value of Honey—Its Adulteration and Analysis—Prof. H. W. Wiley.

President's Address—E. Whitcomb.

Secretary Mason announces that since his last notice was published about rates, the Western Passenger Association has written that the rates in their association will be one fare for the round trip plus \$2.00, added to the rates charged by the other association thru whose territory the person may travel. By enquiring of the local station agent, any one may learn the rate.

For any further information, address Secretary Mason.

Selling Honey in the Home Market.—A very interesting article is one by C. Davenport in the Bee-Keepers' Review. He thinks by once finding customers for 10,000 pounds of honey he could hold the trade right along, but then comes a failure of the crop, and he has not found it to pay to buy from other bee-keepers, and so the trade is lost. He is strong on advertising in the local papers. One year, after the white honey harvest was over, he had 4,000 pounds of mixt amber and dark extracted honey beyond what he needed for his regular customers. Sending the honey to Chicago would net him only 3 cents a pound at wholesale,

and the home market was glutted and prices badly cut. He put an advertisement in his own and near-by towns, saying what the honey was, and that while it lasted he would sell 18 pounds for a dollar. Right below this advertisement was a notice from the leading banking firm of the town, saying \$100 reward would be paid if any honey sold by C. Davenport was not the pure article gathered from the flowers. A deposit of \$100 in the bank secured this latter notice.

Result: He sold all he had, and some 500 pounds more that he bought. Customers came 20 miles and more, and many sent by friends and neighbors. He made a nice profit over what he would have done by selling at wholesale. He has a class of customers who pay 17 cents apiece for sections which weigh less than a pound, their only concern being to get the best honey direct from the apiary.

Tin Cans vs. Barrels for Honey.—At the risk of being somewhat monotonous on this subject, we wish to refer to an illustration bearing directly upon it, which came under our observation about two weeks ago.

We were called over to see a shipment of honey that was sent in barrels from a Mississippi bee-keeper to one of the Chicago commission men. There were two large barrels holding 600 pounds each, or about 1,200 pounds of honey when they were started from the Mississippi railroad station, but when they arrived here there was only 250 pounds of honey left in them. The barrels look good and strong, and had no evidence of leakage at the bung-holes, but one end of each barrel had the appearance of having leaked. We think the barrels were shipped standing on end.

It was certainly a big loss of honey, and we couldn't help thinking that had the shipper used cans there would have been no trouble. At least not all of the 20 cans that would have been needed to hold the honey would have leaked.

We are still in favor of cans, and we believe the Mississippi bee-keeper will be like-minded hereafter. But it is a rather costly experience for him.

The Market Price of Honey.—Mr. H. S. Jones is a bee-keeper of some 50 colonies in this (Cook) county. Naturally, of course, he is somewhat interested in the price of honey. The following, dated July 19, relates a little of his recent personal experience, and also contains a few suggestions to honey-producers:

FRIEND YORK:—Last week I called upon a certain commission man on South Water street, Chicago. Having made myself known, we started in on the honey-business. My first question was, "How much honey have you on hand?"

ANS.—"Just those few cases of buckwheat; no new honey in yet."

QUES.—"What will be the price of comb honey this season?"

ANS.—"I could sell some first-class honey for 13 cents per pound."

QUES.—"That seems to be a low price for first-class goods."

ANS.—"We expect a big crop this season, and the price will be lower."

QUES.—"Do you know that several bee-keepers have lost all, or nearly all, their bees?"

ANS.—"Oh, yes; but there are plenty left to gather the crop."

This same party wanted me to send him some fine comb honey at once, for the small sum of 13 cents a pound, with a low market. It seems to me there is something wrong, somewhere. Mind you, the market is perfectly dry—no honey in to offer to buyers, still the price is away down for first-class goods! It is quite different with fruit. The first strawberries in the market go away up, and come down to a price where every one can buy. Where is the difference?

Can any one inform me where this commission man got his price of 13 cents? Who gave it to him? Or did he just set that price to suit himself? I cannot understand why, here in a city like Chicago, the price of comb honey should

be at such a low figure; and unless the bee-keepers keep up with the sugar trust, etc., they will have to give their honey away and a silver spoon to eat it with. Come, come, bee-keepers; to the front, and make a firm stand for your rights. Everything is advancing in price—why not our sweets, which we work hard for?

Is there not *one* amongst us who would dare get up and start a honey exchange, whereby all bee-keepers could become stockholders, and share in the profits of what the commission men get? The florists have their exchanges, the fruit-growers have theirs. It pays them first-class. The orange-growers have their exchanges, where the fruit is sorted, repacked and sold. They are scattered all over the country, so that no one point becomes overstocked, and is also never out of stock. The prices are governed by the quality of the fruit.

That is what the bee-keepers want. Let *them* set the price on their goods, as any other producers do, giving each grade a fair, living profit. Until we have something of this sort the prices will be low, and lower still. We must get up and establish the price of honey, and not leave it to one man to say what the price of honey shall be.

Come to the front, one and all, and see what can be done before it is too late.

H. S. JONES.

There is no doubt about there being a good deal of truth in what Mr. Jones says, and it seems to us that the United States Bee-Keepers' Association could organize a department to inaugurate a plan whereby at least the honey of its own members could be handled more satisfactorily to them than has been the rule heretofore. It would be necessary to have a manager, in some large city (perhaps Chicago), to whom would be shipped the honey, or at least some of it that might need grading and repacking. Doubtless much of it could be graded properly before shipping, and then have it go direct to other cities where needed.

Surely, there are brains and business capacity enough in the present management of the Association to start a plan that would develop into what the honey-producers ought to have in order to dispose of their crops to the best advantage.

Planting Basswood (Linden) for Honey.—Editor Hutchinson grows poetic in an apostrophe to "Lovely Linden," and then takes the poetry all out of it by discouraging the idea of planting a linden orchard with a view to profit. He gives a report from A. I. Root, perhaps the only man who ever put as many as 4,000 lindens in one plantation. The trees were planted in the spring of 1873, one rod apart, and the ground cultivated for two years, and no other crops have occupied the ground since the trees were planted. The apiary among the lindens has given much more honey than the home-apiary two miles away, but only a small part of the trees has done much blooming. This is perhaps because the land is low and wet, besides being poor. E. R. Root adds that one great fault was that sprouts were allowed to grow around the bottom of the tree.

Mr. Hutchinson thinks the only feasible plan is to own the land upon which the lindens grow, otherwise the woodman's ax is pretty sure to ruin the bee-keeper's pasturage.

Uses for Beeswax.—In the Northwestern Agriculturist we find the following recipes which employ beeswax as an ingredient:

GRAFTING-WAX.—To make grafting-wax, melt four pounds rosin, and when hot add one pound each of beeswax and beef tallow. When all is melted, pour into cold water and work the same as you would taffy.

COMMON SEALING-WAX.—Common sealing-wax may be made by slowly melting four pounds of rosin with one pound each of best gum shellac and beeswax. Cool in thin sheets which can be easily broken.

DRUGGIST'S SEALING-WAX. A good quality of druggist's sealing-wax is made by melting one and a quarter pounds of rosin and adding one ounce each of beef tallow, lard and beeswax. When all is melted stir in one ounce of American vermilion. For use, melt a piece of this wax and dip the cork bottles into it.

Your Help Wanted to Increase The List of Subscribers to the Old American Bee Journal?

We really believe that if **ALL** the present readers of the American Bee Journal were so inclined, they could help to double its regular list of subscribers before Sept. 1, 1899—or during the next 5 or 6 weeks. We do not find any fault with what our subscribers have done in the past toward increasing the list of Bee Journal readers—for they have done nobly—but why couldn't the doubling of the list be accomplished within the next month? We surely think it could be done, and in order that it may be easier for those who help in it, we will make a **SPECIAL NEW SUBSCRIPTION OFFER**, and also pay all who will aid in securing new subscribers. Here is the offer:

Six Months for 40 Cents to a New Subscriber....

Yes, we will send the American Bee Journal **EVERY WEEK** from July 1, 1899, to Jan. 1, 1900—26 numbers for only 40 cents, to a **NEW** subscriber. In addition to this we will send to the present regular subscribers, for the work of getting new 6-months' readers, their choice of the premiums mentioned below, but no premium will also be given to any new subscriber on these offers, under any circumstance:

For **1** New 40-cent Subscriber
Sending — Your choice of one of the following list:

Wood Binder for a year's Bee Journals.
Poultry for Market.
Our Poultry Doctor.
Capon and Caponizing.
10 copies York's Honey Almanac.

For **2** New 40-cent Subscribers
Sending — Your choice of one of the following list:

Dr. Howard on Foul Brood.
Monette Queen-Clipping Device.
Bienen-Kultur (German) by T. G. Newman.
Dr. Tinker's Bee-Keeping for Profit.
Pierce's Winter Problem in Bee-Keeping.
Bees and Honey (160 pages, paper) by Newman.
20 copies York's Honey Almanac.

For **3** New 40-cent Subscribers
Sending — Your choice of one of the following list:

Bees and Honey (160 pages, cloth) by Newman.
Bee-Keeping for Beginners, by Dr. J. P. H. Brown.
Bienenzucht und Honiggewinnung (German) by J. F. Eggers.
Advanced Bee-Culture, by W. Z. Hutchinson.
30 copies York's Honey Almanac.

For **5** New 40-cent Subscribers
Sending — Doolittle's Scientific Queen-Rearing.

For **6** New 40-cent Subscribers
Sending — Prof. Cook's Bee-Keeper's Guide.

NOW FOR A GRAND PUSH FOR NEW SUBSCRIBERS!

It seems to us that with the above low rate to new subscribers, and also the premiums offered, we should get such a landslide of new subscriptions as will make us sweat to care for them during the next few weeks without any help from the hot weather. **WE** are ready now to enter the new names and mail the premiums. Are **YOU** ready to go out and get them, and then send them in?

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Another Offer: Golden Italian Queen Free!

For Sending 2 New Subscribers!

Any one sending us **TWO NEW SUBSCRIBERS** to the Bee Journal for one year (with \$2.00) will receive, as a premium, by mail promptly, a **Warranted Golden Italian Queen-Bee**, valued at 75 cents; or, send us **ONE** new subscriber for a year, and 30 cents more (\$1.30 in all), and the queen will be mailed to you.

Address, **GEORGE W. YORK & CO.,**

118 Michigan Street, CHICAGO, ILL.

Root's Column

GLEANINGS AT REDUCED RATES....

We do not need to tell you about our journal, for it will speak for itself; but as an extra inducement we make the following low offers:

Offer No. A.

For 25 cents we will send GLEANINGS IN BEE-CULTURE from the time your subscription is received until January, 1900. If you send in your order promptly you will get 6 months for only 25 cents.

Offer No. B.

For \$1.00 we will send an untested Italian Queen worth 75 cts. and GLEANINGS IN BEE-CULTURE one year.

Offer No. C.

For \$1.00 we will send GLEANINGS IN BEE-CULTURE the rest of this year and all of next year, that is, from the time your subscription is received until January, 1901. The sooner you take advantage of this offer, the more numbers you will receive.

Offer No. D.

For 50 cents we will send GLEANINGS IN BEE-CULTURE 6 months beginning July 1 and Vol. I of Gleanings. This is for the year 1873. There are many interesting things. There are 12 articles on "Starting an Apiary," and while some of these may not be practical now, there is much valuable information and it gives a good idea of bee-keeping at that time. Our supply is limited and of course we cannot continue this offer long.

Old as well as new subscribers may take advantage of these offers, but all arrearages on back subscriptions must first be paid at \$1.00 per year.

ADDRESS

**THE A. I. ROOT CO.,
MEDINA, OHIO.**

In the multitude of counsellors there is safety. Prov. 11-14.

Judging the Condition of a Colony by External Symptoms.

Query 98.—Can you by external symptoms determine the condition of a colony without removing any of the combs?—ILLINOIS.

- Dr. C. C. Miller—No.
- Mrs. L. Harrison—Yes.
- J. A. Green—Very often.
- J. M. Hambaugh—Not always.
- Rev. M. Mabin—Sometimes, yes.
- J. A. Stone—Yes, to a great extent.
- Chas. Dadant & Son—No, not always.
- G. M. Doolittle—Generally, yes. Minutely, no.
- C. Davenport—Sometimes to some extent.
- O. O. Poppelfon—Some of the conditions, but not all.
- E. Whitecomb—In many cases, yes; others, no.
- P. H. Elwood—No. Haven't any X-ray apparatus.
- D. W. Heise—Some conditions I can, and some I can't.
- Eugene Secor—Generally, for most practical purposes.
- C. H. Dibbern—Yes, almost to a certainty, every time.
- Dr. A. B. Mason—Can determine some conditions, but not all.
- A. F. Brown—Generally, yes, tho there are exceptions to all rules.
- R. C. Aikin—In a general way I can, but outside diagnosis doesn't answer all purposes.
- Dr. J. P. H. Brown—In a general way you can; but to get positive knowledge you must go *inside* of the hive.
- E. France—No. But can tell a weak colony from a strong one, and give a pretty good guess as to other conditions.
- Emerson T. Abbott—Experience will enable one to form a pretty correct idea, but I cannot explain on paper how it is done.
- Prof. A. J. Cook—In some measure, but not accurately. You can measure its strength and give a good guess at the cause, if weak.
- W. G. Larrabee—I can almost always tell by looking at the top of the frames without removing any, but not by looking at the outside of the hive.
- J. E. Pond—I cannot, any more than I can tell what one had for dinner by counting his vest buttons. I can only determine conditions by examination.
- Mrs. A. J. Barber—Not invariably. I can give a good guess; but sometimes there are conditions that one cannot determine except by a close examination.
- S. T. Pettit—If they are short of stores I can determine that by lifting the rear end of the hive. If they are weak or queenless I can give a pretty good guess by outside symptoms.
- G. W. Demaree—Well, I can tell almost at a glance if there are good reasons from external appearances for practical investigation of the internal condition of the colony. Any time excepting in the swarming season I can tell from external appearances when a colony is queenless.
- E. S. Lovesy—Yes, in going around among the bee-keepers I can generally tell the condition of their bees before opening the hives, but there is not room in the "Question-Box" for explanations. But

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |

when you see a colony with a large amount of bees rushing in and out of the hive, carrying in honey and pollen, as a rule there is nothing serious the matter with them.

Mrs. J. M. Null—To a certain extent, but examinations are necessary to a thoro knowledge as to conditions, as stores, queenlessness, and preparation for swarming. Where movable bottom-boards are used this can be done by raising the hive and looking from the bottom upward.

Adrian Getaz—Yes, I can usually. That is, near enough to decide if there is something wrong or not, and what it is. But it takes close observation and daily visits, as the conclusion is reached more by the change of the conditions from one day to another, than by the actual appearance of the colony at a given time.

R. L. Taylor—Yes, to a large extent. Thus it is easy to tell in April when the bees are at work whether a colony is queenless, but I cannot tell when a young queen, in a colony from which a swarm has issued, begins to lay. In April and May I am certain of the condition of 95 percent of the colonies without opening a hive.

Bees Wintered Well.

My queens of this season's rearing are inferior. Queens were extra good last season. I wintered in a dugout 51 colonies without loss—not enough bees on the cellar floor to bother about sweeping up. All queens were alive and healthy in the spring. Alice made nests in the empty supers filled with planer chips, but did not dare enter a hive. Bees were like crickets all winter.

I have taken off some honey from raspberry bloom. White clover is not yielding yet.
JOHN ARMSTRONG.
Chippewa Co., Wis., July 5.

Fall Honey Prospects Poor.

The winter of 1898 I lost 50 percent of my bees in the cold spell of February, the balance coming out weak in the spring. April and May were good for the bees to build up in stores; June and July were too dry. The bees have not made a living. The prospect for a fall flow is poor, as we had a freeze June 30, that froze corn and potatoes, and did lots of damage. White clover is scarce, and linden only lasted three days on account of dry weather. I used Mr. Raymond's plan for increase, to perfection.
Success to the American Bee Journal.
Hardin Co., O., July 15 F. McBRIDE.

Moving Bees a Short Distance.

My bees are doing very well. The alfalfa is coming into bloom the second time, and I am in the middle of a 3,000 acre field of it, and the prospect is flattering for a good flow of honey.

I moved my bees this spring about 100 yards, to set them under young cherry trees, and for the benefit of those who may want to do the same, I will tell here how I did it. I just took them up and carried them to their new stands, and the next day they went back in considerable numbers; I let them alone till the afternoon, and then I set three or four hives full of combs on the old stands that I moved from, and the bees gathered on them abundantly, when I carried them and put them into the weakest colonies I had. In that way I made the colonies nearly equal, and instead of moving doing the bees any damage I am certain it was a benefit.

On the second day after moving I let them alone in the forenoon, and after dinner I took two hives full of frames of combs with some honey in them and let all the bees there were hovering around their old

Bees by the Pound

YOUR OPPORTUNITY!

We have arranged with a large bee-keeper in Cedar County, Iowa, to furnish ONE-FRAME NUCLEUS OF BEES WITH WARRANTED PURE ITALIAN QUEEN and ONE POUND OF PURE ITALIAN BEES—all for only \$2.00; or in lots of five at \$1.80 each. There are only 75 for sale. Better order quick if you want any. If more of the queens are wanted, these can be had at 75 cents. All queens reared by the Double-wall process.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

camp-ground go into the two hives, and there were enough to make two good colonies. I just left them in the hives, and at dark I carried them over and let them remain in the hive, and in two or three days I gave them queens; now they are filling their supers with honey, and are as good colonies as I have. So, you see, one can move bees and not lose any, but improve them instead.

The bees didn't go back to amount to any thing on the third day, and I had no more trouble with them, but all boxes and pieces of boards, in fact everything, must be cleaned off the old yard, so they will have nothing to cluster on. I moved 37 colonies.
A. J. SNOWDEN.

Buffalo Co., Nebr., July 16.

Honey Crop Light.

The honey crop here is light. When the clover was on it was too cold; and when the linden came it was too late. Thistle so far is yielding but little.
S. T. PETTIT.

Ontario, Canada, July 18.

But Little Swarming and Honey.

Bees are working pretty well now. There has been scarcely any swarming in this part of the country this year, and but a light honey-flow the forepart of the season.
Will Co., Ill., July 19. A. B. METTLER.

Double-Wall Hives.

I notice Cogitator says, on page 421, that my double-wall hives are like fencing a pasture with no pasture between. I have tried the other double-wall hives and given them up years ago, for reasons best known to myself. I would not say anything about other people's way of doing things. Then, on the other hand, I do not want other people to do my way. A colony of bees that would not winter thru our winters in my

hives would not be worth wintering. At this date, here in Cook County, I have taken off two full supers of fine comb honey from each of several colonies. Who can beat that?
H. S. JONES.

Cook Co., Ill., July 19.

An Old Acquaintance.

Bees wintered well here last winter. I lost none from 40 colonies. Our main honey plant is alfalfa, which we have in abundance. The honey-flow is light now, but the outlook is good. The second crop of alfalfa is just beginning to bloom.

I have a long acquaintance with the American Bee Journal, my father, Dr. N. P. Allen, of Kentucky, having taken it for about 30 years. He was at one time President of the North American Bee-Keepers' Association, while Thomas G. Newman was editor of the Bee Journal. Success to you, Friend York.
J. C. ALLEN.

Finney Co., Kan., July 13.

Too Much Rain.

I haven't taken a pound of honey yet this year, and prospects for a fall crop are very poor. It rains so much there doesn't seem to be any honey in the flowers.

Sauk Co., Wis., July 19. H. H. PORTER.

Storing No Honey.

Bees in this vicinity are storing no honey at all. We had a good flow of honey-dew in May, and lots of swarms, but it rained nearly every day during the basswood season, and after that the nectar seemed to dry up entirely. The vast areas of black sumac here is not worth a cent. It may be that cotton will help us out.
LEE LONG.
Choctaw Nation, Ind. Ter.

Very Light-Colored Bees.

I have just been watching a colony of bees, and saw a large number going out, and of the lightest-colored bees I ever saw. They are many shades whiter than any albinos I ever saw. Just look at them thru a magnifying glass.
HENRY ALLEY.
Essex Co., Mass., July 16.

[We received the sample of bees, and they are indeed the lightest colored bees we ever saw. Personally, we prefer the yellow bees for looks.—EDITOR.]

Did Well at Swarming.

My bees have done well at swarming. I had 13 colonies in the spring, lost none in the winter, and now I have 45. Seven were doubled up, and 5 left for the West. There is not much honey. I do not know how to work bees very well, as I am young at bee-keeping tho old in years.

Mrs. PETER R. DICKSON.

Winona Co., Minn., July 14.

"Hand-Shaking Contagion."

No, Mr. Cogitator, I shall not attempt to inflict statistics regarding promiscuous hand-shaking, as per your suggestion on page 421. A reasonable amount of it could be easily given, however, but a little reflection as to possibilities will prove sufficient to clinch the note of warning to which you very good-naturedly refer.

It need only be considered how minute a quantity of virus is necessary to inoculate the human system, to find the key for many infections. We may breathe in an infinitesimal amount with the air we inhale, to prove sufficient for the production of most dire diseases. So, a very little exudation from an infected hand coming in contact with some abrasion on a neighbor's fingers is quite sufficient to impart some of the diseases to which the human skin is liable, especially those having affinity for the hands.

Cogitator need not be reminded that eruptions on the skin are simply manifes

tations of a more or less seriously contaminated blood, making effort to eliminate its impurities upon the surface. This is Nature's attempt at freeing the system of unwelcome substances, whether inherited or acquired. Now, there is no difference how the trouble occurs, whether the poison is attached to a door-panel or a big brass knob, if it comes in contact with an abraded portion of the body, so that it may be absorbed, contagion is all too likely, but, of course, not so probable as direct contact with the warm, moist, and active skin of the hand.

So clearly is the danger appreciated that now public functionaries, when compelled to recognize the multitudes, sensibly wear a light pair of disinfecting gloves during the general hand-shaking performance. The custom especially prevails in European court introductions, and other formal occasions.

As more thoughtful attention is given this subject, our democratic officials will learn to recognize its importance, and gladly imitate its more sensibly aristocratic brethren "over the drink."

There, dear Cogitator, you have impelled me to write nearly a small book in refutation of your doubts, and that, too, of all other questionable mediums for the purpose, in a bee-paper. Now be good.

DR. PEIRO.

Flowers Scarcely Visited by Bees.

I had the first swarm of the season July 11, and took a heap of comfort having them, as they clustered low on a grapevine. My joy was of short duration, for they were no sooner in the hive than out they came pell-mell, and returned to their old hive.

Our colonies have made a living, and reared large families, and yet spend the larger part of each day clustered in their porticoes. The bloom of white and sweet clover is quite plentiful, and yet a bee is seldom seen visiting them. Did last winter's freezing destroy the sweetness? There was a flow of honey for a day or two, during basswood bloom, tho a portion of it may have been from the buckbush.

Bees have not carried water for a fortnight; during the forepart of the season they could be seen at almost all hours of the day around the hydrant, but not a single bee is to be seen there now.

Vegetation is very rank from frequent showers, and there may yet be a fall flow of nectar. Bee-pasturage yearly grows less, by the drainage of wet lands, and the bees' only resource is the roads and hedges. "What will the harvest be?" will soon be answered.

MRS. L. HARRISON.

The Bee-Keeper's Guide

Or, Manual of the Apiary,
—BY—
PROF. A. J. COOK.

460 Pages—16th 1899 Edition—18th Thousand \$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year!

Send us TWO NEW SUBSCRIBERS to the Bee Journal with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, July 19.—A little comb honey is coming and the best white in pound sections brings 13 cents; some of it is not properly sealed and leaks from those few uncap cells sufficiently to stain the cases and thus detract from its value. Amber grades, 10 $\frac{1}{2}$ to 11 cents, and dark, 7 $\frac{1}{2}$ to 8 cents. Extracted, white, 7 $\frac{1}{2}$ to 7 $\frac{3}{4}$ cents. Amber, 6 $\frac{1}{2}$ to 7 cents. Beeswax, 26 $\frac{1}{2}$ to 27 cents, and sells on arrival.
R. A. BURNETT & CO.

KANSAS CITY, July 7.—A small shipment of new comb honey on the market is selling at 14 $\frac{1}{2}$ to 15c. Good demand. C. C. CLEMONS & CO.

NEW YORK, June 9.—Demand good for extracted honey, all kinds, and same finds ready sale at the following prices: Fancy, 7 $\frac{1}{2}$ to 7 $\frac{3}{4}$ c; choice, 6 $\frac{1}{2}$ to 6 $\frac{3}{4}$ c; fair, 5 $\frac{1}{2}$ to 6 $\frac{1}{4}$ c; common, 5 $\frac{1}{4}$ to 6 $\frac{1}{2}$ c per gallon. Some demand for comb honey at from 11 $\frac{1}{2}$ to 12c for white, and 9 $\frac{1}{2}$ to 10c for amber. No more demand for dark. Beeswax dull at from 25 $\frac{1}{2}$ to 27c per pound, according to quality.
HILDRETH & SEGELER.

SAN FRANCISCO, July 12.—White comb, 10 $\frac{1}{2}$ to 11c; amber, 7 $\frac{1}{2}$ to 9c. Extracted, white, 7 $\frac{1}{2}$ to 7 $\frac{3}{4}$ c; light amber, 6 $\frac{1}{2}$ to 7c. Beeswax, 26 $\frac{1}{2}$ to 27c.

Only moderate quantities are arriving of either comb or extracted, with no prospect of the market being heavily burdened with offerings any time this season. Business is mostly of a jobbing character, and for such transactions the market is firm at the quotations. Some extracted of superior quality is arriving from Monterey County.

CLEVELAND, July 22.—Fancy white, 13 $\frac{1}{2}$ to 14c; No. 1 white, 12 $\frac{1}{2}$ to 13c; A No. 1 amber, 10 $\frac{1}{2}$ to 11c; No. 2 amber, 9 $\frac{1}{2}$ to 10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c.
A. B. WILLIAMS & CO.

BOSTON, May 17.—Fancy white, 12 $\frac{1}{2}$ to 13c; A No. 1, 11 $\frac{1}{2}$ to 12c; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7 $\frac{1}{2}$ to 8c; light amber, 6 $\frac{1}{2}$ to 7c. Beeswax, 27 $\frac{1}{2}$ to 28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is liked at this season of the year.
BLAKE, SCOTT & LEE.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11 $\frac{1}{2}$ to 12c; some very poor selling at 6 $\frac{1}{2}$ to 7c, and dull. No more business in honey before the opening of the ensuing season.
BATTERSON & CO.

OMAHA, July 18.—Altho first receipts of new crop Southern honey were recorded early in June, there has not been any regularity about them since. A straggling lot of comb turns up now and then, and, when quality is choice to fancy, is eagerly picked up at 14 $\frac{1}{2}$ to 15c. A little lot of 18 $\frac{1}{2}$ crop was received a few days ago and went at 13 cents, quality not above choice. For extracted there is not such an urgent demand, still, 7 $\frac{1}{2}$ to 8c would be obtainable in a small way. The heavy buyers will hold back until later in the season, expecting to purchase on about the same basis of values as last year. Early shipments of all the comb that can be gotten out is certainly advisable; there will not be any chance of holding out with present quotations after the first demand is satisfied.
PEYCKE BROS.

DETROIT, July 15.—No old honey to quote, and no new offered. Prices are liable to rule higher as crop is short. The abundance of bees wax will no doubt help the crop of fall honey. Beeswax in good supply at 23 $\frac{1}{2}$ to 24c. M. H. HUNT & SON.

BIOGRAPHICAL.

Mrs. A. J. Barber and Son "Flake."

The principal subject of our sketch this week is perhaps the best known lady bee-keeper in Colorado. She is also a very successful apiarist. It affords us no little pleasure to present Mrs. Barber, and her young son, to our readers. She has this to say in reference to them and their work:

I was born in Oregon, in 1854, and was brought up in California, Utah, Wyoming and Idaho until 14 years of age. Then we went to Kansas. I attended school at St. Mary's Academy, in Leavenworth, for a time, then we settled upon a farm. In 1876 I came to Colorado, and in 1878 we settled here in Montezuma County, which was a new place. At that time there were only five white women here.

In 1882 I was married here to H. M. Barber. In 1890 my husband bought two colonies of Italian bees as an experiment. We didn't expect much of them, as we thought the altitude too great (7,500 feet) for them. We got them in the fall, and it was decided that I should have the care of them. I sent for the "A B C of Bee-Culture," and studied it all winter. In the spring I got another colony, and began.

I had never looked into a hive before, but soon became so fascinated with the work that I could talk of nothing but bees. In the fall, I had 16 colonies from the three, besides honey for the table. The next year I bought some more, and in the fall I had 67 colonies, in all kinds of hives but

good ones. I sold about 1,500 pounds of honey that year, and was fully convinced that I knew all about bees that was worth knowing!

About that time one of our neighbors, who had gotten bees from Durango, told me that his bees had died, and he wanted me to put bees in his old hives. I told him to bring his hives, and I filled them for him, and at the same time got 10 of my own colonies infested with foul brood. I treated

the bees and saved them, and saved the honey also, to feed the next spring. I boiled that honey and fed it early the next spring, and in June the whole apiary was rotten with foul brood. I treated them, and got them into dovetailed hives. They were so weakened that I doubled them back to 30 colonies. Then I realized that there were many things that I could learn about bee-keeping, and every year since then I am finding out how much I don't know about bees.

We have fair crops, and have never had a failure. We have from 10,000 to 20,000 pounds a year, of comb and extracted honey. We keep from 100 to 175 colonies.

My little boy, who is now not quite 14 years of age, and rather small, for several years has been my helper in the bee-business. For the last four years he has had charge of an apiary every day in the swarming season. We clip all

Mrs. A. J. Barber.

Flake Barber.

queens, and when I am at work at the home apiary he goes on his wheel to the out-apiary three miles away, and watches for swarms. He catches and returns the queens, and marks the hives so that I can treat them the next day when I visit that apiary. When I visit the out-apiary he works at home. Last summer he had as many as eight swarms some days, and managed them all nicely. He also helps in extracting, by uncapping or turning the extractor, or filling pails. In short, he is serving a regular apprenticeship in bee-keeping, and is busy most of the time. He is a member of the Baptist Church, and an active member of the Baptist Young People's Union.

We do all the work with the bees. There are times

when we call in other members of the family to scrape sections, nail up fixtures, and take the honey to market.

I am still in love with the business, and would heartily recommend it to any woman who is situated so that she can engage in it, provided she has lots of patience, grit and energy.

MRS. A. J. BARBER.

CONTRIBUTED ARTICLES

Extracting and Ripening Uncapt Honey.

BY C. P. DADANT.

I HAVE received the following request for information, which I will answer in the American Bee Journal:

MR. DADANT: I am seeking information. Will honey extracted before being capt be all right, provided it is put into tanks and ripened? Will this discourage the bees from working and storing?
J. C. T., Miami, Ohio.

We have made extracted honey our specialty in keeping bees for nearly 30 years, or almost since the invention of the honey-extractor; but we have never aimed to extract unripe honey.

Our reason for preferring to produce extracted honey, even tho it is of less ready sale, and of lower price than comb honey, is that we have so many different things to look after—so many irons in the fire that we find it next to impossible to manage five apiaries with limited help when producing comb honey. The successful managing of a comb-honey apiary requires constant supervision in order to produce honey of the best quality and appearance. Every season the hives must be supplied with a fresh lot of sections, and as fast as these are filled they must be removed and replaced with empty ones, so the combs of sealed honey may not be soiled by propolis and the marks of the passage of the bees—travel-stains, as they are called. Then the product of the apiary must be disposed of during the following winter, for comb honey that has been kept over a year is but a second-grade at best, as there is always more or less leakage and soiling of the sections.

On the other hand, we find that the production of extracted honey lessens the labor. The hives are readily supplied at the opening of the honey season, with the supers and empty combs which have been set aside from the previous crop. One apiary after another may be fitted out in this way with little labor, and one apiarist is sufficient to care for five apiaries, with some time to spare for other work except a few weeks in a very plentiful harvest. If he is accustomed to handling them, and can readily gauge their capacity at sight of the colony, he usually can supply each colony with the amount of surplus-room that it is likely to need for the entire crop, except in extraordinary seasons. And as there is not so much tinkering as with the sections, additional supers, when needed, are soon supplied. When the crop is over, a crew of three to five men takes up the crop in a few days, and the profits are realized without a great expenditure of labor.

Then we find that it is not always advisable to crowd one's honey upon the markets. When we have a large crop many others are successful as well, and prices are low. If we are able to hold our honey we often realize much better prices, for a season of scarcity often follows an abundant harvest. These are the main reasons that have induced us to extract our crops.

We do not wish to be understood as advising others to follow our course, and we believe that each man should act as circumstances direct him; he must be his own judge, and decide on his course accordingly, taking into account his facilities for selling and disposing of his crop, as well as his ability or willingness to put in the labor at taking care of the crop. The average bee-keeper, who has but one apiary, is usually a careful man, neat and precise in his habits. The minutiae of comb-honey production rather pleases him, he delights in producing fine honey, well sealed, in beautiful white comb, and that is why a great majority of apiarists will always prefer the production of comb honey, even if it was not of more ready sale than the extracted honey.

But I am wandering away from the subject of the en-

quiry above. My purpose was to show why we have but little experience in extracting unripe honey, since we always make it a rule to leave the honey on the hives till the crop is over, except, as I said before, in extraordinarily wonderful seasons, when it is impossible to furnish the bees enough room in any reasonable amount of supers. But in such extraordinary seasons the honey is usually more easily ripened than in the years of scant crop, especially when the scant crop is caused by a superabundance of moisture.

The late Chas. F. Muth, who so lamentably ended his career a little over a year ago, was a very practical bee-keeper, as well as one of the most extensive, if not the most extensive, honey-dealer in the entire world, and I have often heard him say that he did not care how unripe the honey was, it could be easily ripened by keeping it in a hot place in an open vessel during the hot weather. His method was to use an extractor-can covered only with a light cloth or muslin, kept in an attic until the end of the summer. I will confess that we have never tried this. Mr. Muth had but a few bees, living in the heart of a great city (Cincinnati), and the amount of unripe honey which he harvested could not be much in the way. But if we were to try this method with apiaries numbering 400 to 500 colonies, it would take a very large room and an endless number of large cans. We prefer to let the bees do the work, which we think they can do with much more satisfactory results. The quantity of honey that has to be handled is much less when it is ripe, and the labor much less. The only gain of which we see any possibility in handling unripe honey is the greater ease with which it may be removed, as one does not wait until it is sealed, or till the crop is over, and there is less danger of excitement in the apiary and of robbing during the operations if they are performed while there is still honey to be had. But the latter result may often be attained by beginning the extracting before the entire finish of the crop.

One thing I must emphasize, and that is, that honey does not necessarily need to be sealed to be ripe. A great deal of honey is left unsealed by the bees after the crop, which is as ripe as the sealed honey, and their reason for leaving it in this shape seems to be only because the crop is nearing its end, or is intermittent, and they probably do not see the need of spending time and wax in sealing cells which they think will be emptied of their honey before many weeks.

On the other hand, honey which is sealed by the bees is not always ripe. We have seen many instances of honey fermenting and bursting the caps of the cells, and such honey when found would better be harvested in separate vessels, to be sold separately. We find more unripe honey in our locality from basswood than from any other bloom. For some reason unknown to us we have seen but very little fall honey that was not thoroughly ripened within a very few days after the harvesting of it by the bees.

As to the question whether the taking of their honey will discourage the bees, I would say no. The combs are returned to the hive always sticky with honey, and this seems rather to add a new stimulus to their energy. It has always appeared to us that when the honey was extracted during the flow the bees seemed to work with increased energy, so there would be no objection on that score.

Hancock Co., Ill.

Early California Bee-Keeping—Crop of 1899.

BY W. A. PRVAL.

THE early history of bees in this State dates, I might say, from their introduction into San Jose, then, and still, the garden spot of California. Alameda County, which was then a portion of Santa Clara County (San Jose being the county seat), secured colonies of bees from the Garden City, as the fruit-growers in the latter county, even at that time, recognized the importance of bees in an orchard. So, in the latter 50's and early 60's, Alameda, Santa Clara and Sacramento counties were the home for many years of the bee in this State. Of course, it was not long before adjoining counties became stocked with the little workers. Thus, bees were distributed for a distance north and south of about 150 miles. But Sacramento soon became the center of the bee-business. This was owing mainly to the fact that Mr. Harbison lived there, and was engaged in producing honey, making his patent hive, and, I believe, raising nursery-stock.

The forage along the Sacramento River in those days was excellent. Hydraulic or "placer" mining in the hills

and mountains along the tributaries of the Sacramento had not yet sent down "mountains" of debris to fill the grand Sacramento, so that it was continuously overflowing its banks with every heavy rainfall or sudden thaw of snow in the Sierras. I have not seen it so stated, but I think it was the mines that ruined the bee-business along the Sacramento. For years it did not pay to produce honey there. True, there was much honey produced, but it was from weeds that gave the darkest and rankest sort of nectar. It was often unsalable; only bakers could use it. I presume the slickens from the mines was responsible for the growth of these vile weeds. The good forage had been destroyed for the most part.

The bee-keeper was not the only one to suffer from the hydraulic mining industry. Hundreds and hundreds of acres of beautiful orchards along the Sacramento, Feather, American and other streams were ruined by the overflows caused by the washings from the mines. The rivers were filled with earth rock, and other debris, consequently when there was a freshet the water broke over the river banks and carried vast quantities of sand, rocks, dead trees and other debris into the once fruitful orchards. They were ruined, as it was impossible to remove the sand and debris, and nothing would grow in the sand. (Years later this sand underwent decomposition, and is now able to support vegetation.)

Then grain and vegetable fields suffered almost as badly as the orchards; the difference in most cases being that where the farmer lost one crop the horticulturist lost all his crops, or until such time as he got a new orchard into bearing condition. Often, about the time a new orchard was about to yield the owner a return, another flood would again destroy the labor of years. So, in time, the federal government legislated against the running of slickens into the rivers and streams of the State. If the miner wanted to mine with water he must impound the debris. I think this legislation has been in operation over ten years. It has revived the horticultural interests along the streams that were once blighted.

Thus, to a large extent, honey-yielding flowers again sprang up. Then large fields of alfalfa are raised along these streams. I presume many of them are growing on land washed down from the mines, some or all of which contain particles of the finest kind of gold-dust. With gold at its roots the alfalfa along these streams is now giving the bee-keepers golden drops of honey, which in turn bring him golden nuggets.

It was during the past week that I had occasion to learn about the extent to which the business along the Sacramento has been revived. I saw much of the honey piled up in one of the San Francisco commissions. A few days later it was all sold. It looked very nice. It was alfalfa honey. I am told that while the honey from the San Joaquin valley alfalfa is water-white in color, that of the Sacramento valley is of a very light amber color. I cannot account for this in any other way than that the latter is mixt with some nectar gathered from sources besides alfalfa. The climate of the two valleys is identical, both being very hot in late spring and summer. It is these two valleys that are giving the State its big crop of honey this year. I say "big," for if it were not for these two sources we would have no crop to speak of. The yield in the upper end of the San Joaquin I am told is very good. The alfalfa fields are yielding well. It is destined to be the honey center of California. The yield, I think, this year for the whole State will warrant the bee-keeper getting a good price for his product.

My crop is less than a quarter crop this year. Knowing how to handle honey I managed to get seven cents per pound, less commission. This time last year I was offered three cents for my honey. I would not sell. I told the dealers I would get five before the year was over. In November I sold for 5½ cents. That was something like business. Of course, if I had held on until now I could have obtained a cent and a half more. But I do not believe in holding a product too long. I believe in letting a crop go when you are offered a reasonable price. Give the other fellow a chance to make something. The past spring hay went up to \$18 per ton, owing to the dry outlook of the season. I have friends who were offered this price for barns full of hay. They said no; just wait and we will get \$30, as it is going to be a dry year. A week later the rains came and hay took a tumble. This season's crop is a good one, new hay already selling for from \$8 to \$10.

My advice to any one, unless he can afford it is, don't speculate; you may get burned if you do. Leave it to the Leeters and that class. Even they may die poor by speculating too long.

I hear that some commission houses in San Francisco—one in particular—is working hard among the honey-producers of the State to corner all the honey. This latter house is a Jewish concern, and it hopes to make a big thing in honey. While talking with a representative of a certain house, he said that he was afraid bee-keepers would not send on commission; that they might sell if the honey had not been secured already. I intimated that it might be a good thing for his house to get in and do some buying, too, as it has been doing a big honey-business the past two years. The gentleman told me last week that he sold more honey the past two months than he sold previously in all the years he has been in business, and that's over 20 years.

While at this commission house yesterday afternoon I saw a lot of 53 cases of as fine looking water-white comb honey as I ever saw, that was produced in the Sacramento valley, and which was then being carted out of the store to the railroad depot. Just think, it was being shipt to Los Angeles! If that doesn't appear to be "carrying coals to Newcastle" I am sure I do not know what is. Of course, there was a time, I believe, a quarter of a century or so ago, when this part of the State shipt honey to the lower portion thereof, but that was before it was discovered that the lower counties were a vast bee-garden. Of course, it is the drouth down there that has caused honey to flow southward this year. Perhaps next winter the orange-growers in the northern part of the State may be sending their fruit to feed folks of the city of the Angeles. Strange, is it not, that tho a number of the northern counties up along the Sacramento, as well as Sonoma county, send carload after carload of oranges to the Eastern market, we never see any of them in our markets? They come in before the oranges of the southern portion of the State do, consequently they bring a high price, and the growers take advantage of this fact and send them to market where they will get a high price.

I am working on an interesting case that I may send an account of later. It was where a bee-keeper up north always sent five cases of honey to a dealer in San Francisco. It was bought as "tule" honey—a dark honey that is used by the bakers of that city. It was purchast without being sampled, as every dealer knows what the Sacramento and the San Joaquin river "tule" honey is. It was sent around to the party who was to use it, and almost as promptly returned. The "honey" is different from anything I ever saw; it is as dark and thick as New Orleans molasses, and has something of such taste, too. Yet, on careful examination it would pass for a fruit-jelly. I think if it were put in jelly-glasses it would easily sell for such. I am inclined to think the bees that gathered it had access to a field where apricots or prunes were being dried, and just gathered the juice from the fruit. The man whose bees gathered the honey writes the commission house that it was positively extracted from the hives. I am going to write the producer to find all I can about the locality, etc.

The weather is still disagreeable, tho we had a few hot days up to yesterday evening. The indications are that we are going to have early rains, and possibly much of them.

Alameda Co., Calif., July 20.

Making Increase by a Nucleus Method—The Doolittle-Miller Controversy.

BY G. M. DOOLITTLE.

ON page 418 I find an "Open Letter to Doolittle" by Dr. Miller, near the close of which he says he is about to formulate some questions according to the way he understood "Iowa" to mean when he askt those found on page 198, and he will reply to them, sending them and his answers to the editor, asking the editor to send the same questions to me for my reply, so that the readers of the "Old Reliable" can see how we agree. Well, the questions have arrived, and I am going to say just what I think regarding them, even tho I cannot read the same thing out of "Iowa's" statement on page 198 that Dr. Miller does. Here are the questions as the Doctor understands them:

I intend to increase artificially this year, and for each new colony I intend to start a nucleus by putting in the new hive a frame of brood and eggs and a frame of honey, closing up the two frames, at one side of the hive with a division-board, then giving a sufficient number of bees. I intend to get the bees from the colonies with laying queens, shaking the bees from the combs and giving them directly to the nuclei.

1. How many bees will I have to put into a hive?
2. Will a pint do?
3. Will these bees rear a queen from the eggs given them?
4. Do you think a nucleus formed in this way will be all right?
5. Would it be safe from robber-bees?

Iowa.

ANSWERS. 1. As it is stated that "Iowa" intends to take the bees which he is to use in forming his nuclei "from the colonies with laying queens, shaking the bees from the combs and giving them directly to said nuclei," I would reply that under such conditions *all* the bees there were in any one colony from which they were taken would *not* be sufficient to form a decent nucleus. If any one has not tried this way of working, it appears very nicely in print, but let it once be tried and it will never appear nice after that, for bees so shaken are the most persistent things in trying to get back to "mamma" of anything I ever had to deal with.

The proposition does not even hint at any precautions being taken to keep those bees in the hive with the comb of brood and honey, and unless such precautions *are* taken, there will not remain bees enough in that hive to make a decent nucleus 24 hours later, no matter if two bushels are put in by the plan proposed, for what cannot get back home again will run out of the hive and scatter over the ground, thru the grass and anywhere but stay with those two combs in that hive. I know what I am talking about, for I have tried it many times, even putting them in just at dark, only to find them scattered all over everything surrounding the hive early the next morning, with scarcely a bee inside on the brood and honey.

These being the true facts in the case, the one word "No" very fully answers questions 2, 3, 4 and 5.

Now I want Dr. Miller to turn to his open letter to me and read the last half of paragraph four over again, then tell us where he got any such an idea from my article on pages 370 and 371, that "Iowa" would "lose a queen by the operation." Did not I distinctly state on page 371, that after the hive having cast a swarm was set on the stand previously occupied by the nucleus that the queen was to be let out of the cage, and "allowed to run in her old home"? And did I not make it equally plain that the queen reared in the nucleus was to be shaken with the bees out in front of her hive so that the queen, the bees from the nucleus, and the swarm, might run into the hive together so that no quarreling would result? Don't throw "hypercritical" back at me Doctor, for if you will take pains to read out, what there is in that plan as I gave it there, you will find one of the great and grand principles which can often be used in practical bee-keeping. It is not always easy to make a *swarm* take another queen besides the one which issues with them, for a swarm having its queen taken from them and a new one supplied before it gets fully settled in its new hive or home, is nearly as persistent in leaving the new hive and going back home as are the bees used to form a nucleus by the way "Iowa" proposed to do it, except the few which are engaged in hugging and persecuting the new queen.

Then I want to say a word or two regarding the first paragraph in your open letter. You say:

"I trust I shall always have the grace to receive kindly any criticism made upon any writing of mine, so long as the criticism is given in a spirit of kindness."

You and I profess to belong to the Master, and does not the Master enjoin on his followers that they have grace given them from on high to receive kindly any criticism, or anything else, no matter whether given in the spirit of kindness or not, that they may be true representatives of the meek and lowly Jesus, thus honoring our Father which is in Heaven? And if this is enjoined upon us, shall you and I be disobedient children because some one criticises us in unkindness?

Then I wish to say a word or two regarding the questions I askt you on page 306. You evidently seemed to think that I askt them in a captions way, taking the last two sentences in your reply as evidences, together with the little thrust you give the editor in the first sentence. It would seem that you should have known me long enough to know that I do nothing in a captions way, nor to be hypercritical. Perhaps you were a little soured over your controversy with R. L. Taylor, and so are excusable.

What I was after in those questions was to draw you out on some of the fine or nice points with which a queen-breeder has to contend. Those buying queens are not so content with "generalities" as you are, Doctor, and because only generalities are generally given when giving a description of pure [?] Italians, golden Italians, albinos, etc., queen-breeders are often denounced as "frands, cheats, dead-beats," and everything but honest. To keep my skirts clear of such accusations I keep standing in my circular all the time these words: "I do not claim all the purity of stock that some do, nor lay so much stress on golden bands," and in this way I escape being told that I have misrepresented in the queens I send out. And those ques-

tions were put to you in the hope that you would so specify in your answers that some of the pressure of "breeding to a feather" would be taken off queen-breeders who do not keep what I do standing in their circulars.

Of course, I could have told you what I was after, but that would have detracted from your answers, as the readers would have considered that you were doing something to bolster up the queen-breeders in not sending out queens giving bees markt as they were led to think bees should be markt by what they generally read. Were you a queen-breeder, you would realize something of the pressure brought to bear on such breeders by those who are hard to satisfy.
Onondaga Co., N. Y.

[The condensed answers which Dr. Miller sent with the questions formulated for Mr. Doolittle, are as follows:—
EDITOR.]

DR. MILLER'S ANSWERS TO THE QUESTIONS.

1. A quart of bees might do to start the nucleus.
2. Not so well as a quart, but if the comb is well filled with sealed brood nearly mature, the nucleus might hold its own.
3. Very likely; but I wouldn't give much for such queens.
4. No, it wouldn't be a nucleus that would satisfy me.
5. Not very, if they were troublesome.

C. C. MILLER.

Preparing Extracted Honey for the Market.

(Read by Fred Brown at the California Bee-Keepers' Convention, held in Hanford.)

WE will assume that the bees are gathering honey very fast, as this is the time in which the work is slighted if any, as at such times the honey is often extracted before it is ripe; and that being the case, the honey coming in fast is not allowed to ripen, and when it is put on the market it is not of a good, heavy body, and the flavor is also not the best.

EXTRACTING.—The honey should be at least three-quarters sealed, to insure a good state of ripeness, and even then it should not go into the cans without first going thru the tank.

With the honey thus sealed, we will proceed to the apiary, as there is where the preparation for good, marketable honey will begin. We will have a box with a tin bottom, to put the combs in when they are taken from the hive, the tin bottom will prevent there being any drip, which is a waste, that gathers dirt, and will keep your extracting-room in a muss; the appearance will not be tidy, and there is more liable to accumulate filth in the packing of the honey for the market.

After the honey is thus in the house, and is uncapt and extracted by the extractor, it should be run thru a separator. Allow the honey to run thru the tank, or into a tank. And right here I wish to say that you cannot prepare honey properly without a tank.

GOOD, RIFE HONEY.—And further, I wish to say that I hope that the honey-producers of this association will profit by the lesson taught us by the fruit-packers of this community that it is important to commence right, so there will be no complaint with the honey, as there was with the fruit that has gone into the Eastern market (and by way of digression let me say, there was some very poorly prepared honey that the association placed upon the market last season). Some was very thin, some was very dirty, and was not in a merchantable condition when received by me, and when told to the parties thus offering it, I was met with the answer that if I did not want it there were others in town that would be glad to take it. Such honey, in order to make it marketable, had to be dumpt into a tank and allowed to settle before it was fit to sell at all.

So you will see the necessity of each one that packs honey to have a tank, as poor stuff should not be allowed to compete with good, clean honey. Furthermore, we should have pride enough to want to place only that grade of goods on the market that we know to be absolutely clean, such as would be inviting to a lover of sweets.

HONEY-TANKS. The best style of a tank, to my notion, is one that is not too deep. The one that I use is 6 feet long by 3 feet wide, and a depth of 30 inches. It will hold about 40 hundredweight, and is not very hard to get the honey into, as it is shallow, and another advantage is that it has a good evaporating surface.

Bee-Shed of Thos. Wickersham, Whatcom Co., Wash.

One should, by all means, have the honey-house so arranged that the honey from the extractor will run directly thru the separator, thence to the tank without any handling whatever, and after a short time the honey can be drawn off, and it will be absolutely clean and marketable.

In my honey-house I keep the tank always full, drawing off about five cans at a time. In this way you always have a good pressure to draw from, and then as the honey evaporates it will settle to the bottom, and the thinnest will be on the top, so you are always drawing off the heavy, thick honey.

HONEY-CANS.—When there is a call for a shipment of honey, cans should be washed clean of all the dust or honey that has been scattered on top of the cans, as often is the case in filling.

In every instance the cases should be new and clean; new looking, so the general appearance will be attractive. Do not use oil-cases, by turning them to hide the marks, as it is not a first-class case, and not a very strong one after being once torn up and reconstructed.

Draw a sample of every grade, and have the cases so marked to correspond with the sample, that there will be no difficulty in locating the different grades, as represented by the sample.

FILLING CANS.—I would recommend that the honey be weighed in the cans, putting in just 60 pounds to the can, 120 pounds to the case. If this would work well, which it should, there would be no question about the tare, as it would be checked up at 120 pounds to the case, and nothing said about the tare. We tried this plan one season, and got some in that way, and if I handle the honey for the association this season I will do all that I can to get the purchasers to accept the honey in this style.

The main point to be careful about is to see that the honey is drawn into the cans from a well-filled tank, and that it is well ripened, and that the proper sample has been taken from each lot. Keep the cans very clean on the outside as well as the inside, and there will be little trouble about unmarketable honey.

As a rule, we in the valley have a good, heavy grade of honey, and with a little care we can build up a good demand for our produce, which will bring a ready market and a good figure.

Bee-Keeping in the State of Washington.

BY THOS. WICKERSHAM.

THINKING that a description of some of our Puget Sound methods of keeping bees might be of interest to some of the many readers of the American Bee Journal, I herewith send a photograph of a bee-shed of my own construction, which has proven very satisfactory.

The shed is 60 feet long and 12 wide, and contains 30 hives. At the left end, where you see the window, I have a room bee-tight for storing honey, supplies, etc.

The lattice-work allows ventilation and light sufficient

to make it quite comfortable for handling bees in summer. I have a row of hives on the opposite side of the shed, the same as is shown in the picture. Some seasons I place the hives on the ground in the center of the shed, and pack hay around them for winter; other times I leave them on the summer stands, and have not been able to decide which of the two ways is better. I don't think this is a first-class country for honey in the way of quantity, but I doubt if there is a State in the Union that will excel in quality.

Last season I got 1,800 pounds of fine comb honey from 21 colonies, and increased to 36. The prospects so far this season are very poor, having only two days of sunshine in May and April, and but very little better and still raining in June. It is somewhat discouraging for the manipulation of nectar. However, the bees are in fine shape for work, if "Old Sol" should put in his appearance.

Whatcom Co., Wash., June 2.

[We wish that others would follow

Mr. Wickersham's example, and send

us photographs of things they have found helpful in their work with the bees. We could hardly agree to use all that might be sent in, but we would try to use as many as we could of the pictures, accompanied by descriptions.—Ed.]

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Building Comb from Brood-Frames up thru the Sections.

Why do my bees build up from the frames thru the bottom of the sections? I never had any trouble in that way until last season. I have the "A B C of Bee-Culture," but it doesn't mention a case like it, at least I can't find any. MINNESOTA.

ANSWER.—The trouble likely occurred because the bees were crowded for room, in which case the evident remedy would be timely increase of surplus-room. Too much space between frames and sections might also be to blame.

Nucleus Balling the Queen.

I have a one-comb observatory hive, and about a month ago I put a frame of brood-comb in it (some of the eggs had just been laid) and about 200 bees; the brood became chilled and died, but the bees remained. Last week I secured a virgin queen from a third swarm and put her into the observatory, together with about 400 of her own bees; all seemed lovely and harmonious for three days; the bees started to clean up the comb and to carry out the dead brood, but on the fourth day, when I examined the hive, I found the bees had the queen "balled," and were trying hard to sting her. I took her out for a few hours, gave her some honey, and let her run back into the hive again, when the bees immediately attacked her as before, running wild after her, and I was forced to remove her for safety. Why should they attack her after so many days, and how can I make them accept her? She is still a virgin. CITY.

ANSWER.—It is hard to give a satisfactory "why" for all the antics of bees with regard to queens. Sometimes

they will ball their own queen after she has been laying a year. In such cases it is perhaps to protect the queen, and it is possible they may have had no evil intent with regard to your queen. When you open a hive and find the bees balling a queen that they have before treated peaceably, the best thing is to close the hive promptly, and generally there will be no more trouble.

Extracting from the Brood-Chamber.

We are having a good flow of alfalfa honey brood-chambers full and all in the supers. I have taken off some. How would it do to extract from brood-frames about the time the fall flow from heart's-ease begins? The bees averaged 50 pounds last fall of this dark honey. Would you take all the honey out? Will I run any risk of starving the bees? Your kind of splints on foundation for frames are all right. No sagging now. KANSAS.

ANSWER.—Whether the bees would get enough for winter from the fall flow you can only judge by past years. If you extract their white honey from the brood-combs, you must be ready to feed in case they don't get enough from the dark honey.

Glad you like the splints. They certainly work better for me than wires. But I find it doesn't do to give them to weak nuclei, which take time to gnaw out the sticks. With a full flow, in a strong colony, they are built out beautifully.

Colony with Laying Workers.

I had a queen that patcht her eggs and had drone-brood mixt all about with the worker. I pinch her head. Then I gave them a frame with three sealed queen-cells; a week after that I found they had destroyed the cells and were rearing a queen. I cut the cell out. The next day I hived an afterswarm, which I supposed had a virgin queen. All seemed to be lovely for another week, when I found no traces of a queen, laying worker, or anything of the kind. Then I gave them a fine frame of comb with brood and eggs. I then took the measles myself, and left them to their fate for 15 days. Now they have drone-brood stuck all about thru the hive. What was the matter with them? INDIAN TERRITORY.

ANSWER. The queen was lost in some way, most likely on her wedding-trip, and then laying workers set up business. The best way is to break up the colony and give it to others. You can start a new colony more easily than you can get into proper working order a colony in which laying workers have been doing business for some time.

Early Italianizing—Deep Entrances Preventing the Return of Bees After Moving.

1. In this part of California the bees are all hybrids, and I expect some Italian queens from Eastern breeders this season. Next spring I wish to get as many Italian mated queens into my apiary as possible without too much expense. The climate is very mild here. Can I, early next spring, feed to stimulate these Italian colonies so they will be strong, and part of them have drones before the hybrids have got so far along? Then re-queen the others, and get the queens out and mated before the hybrid drones are out of the comb? They can mate early here, so far as the weather is concerned. It seems to me that if I manage rightly I ought to be able to get as pure Italians as the breeders could produce, without much expense and trouble.

2. I have known it stated that queenless bees will draw out a queen-cell wherever you bruise the comb with a knife-blade under an egg or larva. Is this your experience with Italian bees? I will put one cell in each queenless colony.

3. It having been settled by experience during the past year that a deep entrance to a hive overcomes many drawbacks, the next move is to obtain it. I have seen many ways mentioned but I never run across this plan: Take 16-inch shingles and cut them into strips 7 $\frac{1}{2}$ -inch wide and place one or more (butts out) on each side of the entrance, as per the desired depth. The bees then can run up the sides or go the rear end, then climb up. The expense of fixing a hive is scarcely nothing, and not one bee-keeper in a hundred but has shingles lying about the place.

4. When I have occasion to move a colony of bees I have had success in preventing them from returning to the

old place, by smoking them quite freely when they are coming out after removing the obstruction. Bees seldom leave their home when anything of this kind is too numerous, and I think in the meantime they discover the change in the location. CALIFORNIA.

ANSWERS. 1. Your plan may not succeed as well as you anticipate, but it will probably do a good deal better than to leave matters entirely to their own course. Draw brood from the hybrid colonies to strengthen the best Italians, then furnish plenty of drone-comb, and with feeding you ought to anticipate considerably the dark drones.

If you want to take the trouble, later on in the season, you might try a plan given in the Canadian Bee Journal. Furnish the nuclei that have your virgin queens with plenty of drones of the desired kind. Put the nucleus in the cellar, and after drones in the apiary have ceased to fly, set out the nucleus. If the queen fails to mate, put the nucleus back in the cellar and try it again the next day.

2. I've tried it, but with no great success. Unless you know for sure that the one cell you give is a good one, it is better to allow several and trust to the bees to retain the best. If you give a full colony more than one cell, of course the colony may swarm, but it's better to rear the queens in nuclei.

3. That's an excellent way to enlarge the front entrance and leave the other three sides closed, but I'd rather have all four sides open. The bees don't seem to have any trouble climbing up.

4. I think that's an original plan, and I don't see why it may not be good. A common way is to put a board in front as an obstruction, but a wall of smoke may be a good deal better.

Loose or Tight Bottom-Boards Wedges in Place of Division-Boards.

1. Ought Langstroth dovetailed hives to be nailed to the bottom-boards or left loose?

2. Can I without hurt to the bees take out the division-boards and substitute wedges to facilitate the removal of the frames which are so tightly stuck together that I have trouble removing them? My frames are the Langstroth-spacing kind. VIRGINIA.

ANSWERS.—1. After trying both ways on a large scale, I wouldn't have mine nailed for a good deal of money. Often it is desirable to have one story above another, and you are blockt from anything of that kind if the bottoms are nailed fast. I don't know that any one nails the bottoms on dovetailed hives. When I want a bottom fast to a hive, as I do in hauling, I fasten it with staples, which can easily be drawn out.

2. If you are in a place where propolis is bad and have self-spacing frames of the Hoffman kind, I'm sorry for you. Putting in wedges in place of dummies would only help temporarily. The bees would lengthen out the cells of the outside frame so there would be no extra room. I have some frames of that kind, and I've taken out the dummy and allowed the frames all to spread a little further apart. But I don't want any more frames of that kind where propolis is plenty.

Number of Extracting-Frames—Putting Supers on Swarms.

1. Do you use as many extracting frames for a super as there are brood-frames below?

2. Will not placing supers from the old hive on the swarm immediately after being hived cause them to neglect drawing out the foundation in the brood-frames? I have two in that condition, and I have taken off some full sections from each. ALABAMA.

ANSWERS.—1. Yes, I've spaced frames the same in the super as in the brood-chamber, when working for extracted honey. I think that is the practice of the majority. Some prefer greater spacing in the super, as with deeper cells the queen is not so likely to lay in the super, but it is probably best in any case to use excluders so the queen can't get up.

2. They may go to work more promptly in the brood-chamber if there is nothing above, but that is not generally considered, for super work is more desired than brood-rearing. But if you want to make sure of the work commencing more promptly below, you can follow the plan of those who do not put on the supers until two or three days after hiving.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

SOMETHING THAT AFFECTS THE HONEY-FLOW.

There is a topic which will bear a great deal more talking about than it has ever received, which is alluded to in Dr. Miller's letter on page 396. About time for us to stop saying so much, it was so cold, or so wet, or such a drouth prevailed, that very little honey came in. Of course, severe cold, or constant rain, or very severe and long-continued drouth, arrests the honey-flow; but there is something beyond and different from these which constitutes the main reason. When that mysterious something is right, any one of these three hindrances may hinder greatly, and yet there'll be a fair crop. When that mysterious something is wrong there'll be no flow, tho' all three of the regulation scape-goats could be choked to death with old tinware. Let's find out about it. I think the failure of basswood late years is owing to a fungous disease of the blossoms and leaves; but that, too, is an eccentric, and does not touch the main thing. The true solution must be able to account for the sudden commencement of the honey-flow when nothing plainly visible as to weather has changed. "More things in heaven and earth Horatio," etc.

QUEEN-CLIPPERS AND CLIPPING.

Avaunt there, thou queen-clipper, Prof. Cook! Can't you "jist be aisy" without saying that the wisest of insects, the ants, give us a pointer to clip the queen's wing, when they break off the wings of their queens? The wings of queen-ants are apparently articulated on purpose to break off (like the stems of brittle willows, and the bases of leaf petioles), and the wings of bee-queens are not so articulated. Moreover, we have respectable evidence that ant-queens sometimes break their own wings off; and bee-queens are not led to attempt that. Page 386.

BEE-STINGS AND THEIR EFFECT.

Dadant's article on the bee-sting, page 386, is a very interesting one. I doubted the identity of bee-poison with serpent poison, but did not think before of the evidence he gives stomach revolts violently against bee-poison, but tolerates serpent poison to such an extent that a serpent bite can be sucked with safety. (But is it true that a direct dose of apis nauseates the stomach? And isn't it true that a man bitten by a serpent soon vomits violently?)

I see he repeats the same old caution not to rub or pinch the sting out. Very bad advice, it seems to me. Of course, if one could lift off the sting with the point of a knife *without any delay* it would be better; but practically care in extracting the sting means delay, and delay means a full dose of the poison. I would say, get a sting out *instantly*—with thumb or finger nail, if you have a hand at liberty, otherwise rub it out against the most convenient object—and don't rub so gently as to have to rub the second time. My idea is that the holes thru which the poison flows are too small for pressure to send thru very much additional poison, if one is *quick* enough.

RUBBER RINGS DPT IN HOT BEESWAX.

Mr. Davenport, on page 387, gets a joke off on us, keeps us watching all the way to see the failure he had made, and then tells us that he succeeded. Just dip rubber rings in pretty hot melted beeswax, and honey cannot ooze out under them. It may transpire that this is a very valuable little discovery, and not for honey alone, but for fruit also.

"FOOL NEWSPAPER APICULTURE."

That half-acre of sweet clover under wire netting, to keep the honey unmixt, rather marks the high-water mark of fool newspaper apiculture; but then, yarns of that character don't do us any harm. Page 392.

GLUCOSE—THE GREAT ADULTERANT.

Glucose—editorial on page 393. Ten pounds of liquid lies made for each human being in the nation! We are not obliged to drink the liquid pandemonium that another kind

of Satan's institutions puts out; but these liquid lies we have to swallow. What are we going to do about it? In some countries the answer to that inquiry would be, "Why, bless your soul and body, we can't even think of doing anything about it. They've got on their side the power, and the wealth, and the officials, and the law, too, all they want of it." It is a proper cause of thanksgiving that in our country, when there are monstrous failures of justice, or great triumphs of wrong, there is not so strong a disposition to say we can't do anything about it. Better the American spirit (even if we have to take Judge Lynch thrown in) than the hopeless, sheeplike spirit which some would commend to us.

MRS. HARRISON'S "DARNED" COMBS.

And so when the worms get in Mrs. Harrison's store of extra combs she just darns 'em—not profanely at all (as to no purpose many a masculine craft fellow has oft done), but with the blessed, old, orthodox darning-needle. Interesting to see that so simple a device, faithfully used every ten days, keeps the combs. Page 413.

MAKING FOUNDATION-MOLDS.

The article of Adrian Getaz, on page 402, is as full of suggestions as an egg is of meat. Portland cement much more substantial than plaster to make foundation molds for home use. The tedious of waiting for the material to set can be borne, seeing you are to get a plate as solid as good stone in the end. His flatwise dipping method seems to be excellent. Rock the dipping plank as you put it in the wax—and whisk it quickly wax side up, when you withdraw it—and finally make the sheet drop off itself by plunging the whole thing in warm water. One advantage of the method is that it is adapted to sheeting *small amounts* of wax.

But perhaps the most valuable thing of all is how to drive nails in little pieces of fragile wood—clamp the pieces in a vise while driving.

"THE NECTAR IN FLOWER-CUPS."

Happy to see Mr. Norton again, on page 403; but I'm pretty sure he's wrong in saying that silica in water is only in suspension. Not even sure that he logically covers all the points to prove that thick and thin nectar do not exist in a flower simultaneously. How does he *know* that two contiguous nectar-glands secrete nectar of exactly the same thinness? What's to hinder a ribbonlike film of nectar in a flower from being half dried down at one end, and nearly in original condition at the other? or yesterday's secretion from being thick, when present thin secretions are just beginning to pour out?

FEEDING IN FAMINE SEASONS.

Queens from eggs taken from the *very best* colonies, and subjects for them to reign over from the laggard colonies, not much good for surplus honey. Worth thinking of—but don't tumble in without thinking. This is unent Dadant's article on page 403. It seems the Dadants, when feeding in famine seasons, have never yet failed to get the honey back, and more, too, before the season was over.

CARE REQUIRED BY SHEEP AND BEES.

Twice a week for a sheep, and not twice a season for the bees—the way the average farmer does. Bees to blame. They could stop this nonsense if they would *always* die off under it, but sometimes they don't. This for the Doolittle article on page 404.

TAR SMELL ON FOUNDATION—ABSCONDING.

I think Dr. Miller is wrong, on page 405, in expecting a swarm not to mind the smell of tar on foundation. The lady says some of the swarms object to running in (just what I should expect), and when they don't want to go in it stands to reason that they may not want to *stay* in. One good and easy way to hold bees which are inclined to abscond is to bury the basket and swarm in a suitable pit until near eventide, and then take them out and hive them. They can't well run away in the night, and by morning they may have decided to stay. If also foul-t roody, I'd try keeping them in the pit till they began to tumble down from starvation, and feed them well directly after hiving.

CYCLONE-CELLAR FOR THE BAD BOYS.

And so 8,000 miles from Manila, and less than 2,000 years from the Advent, the first lightning struck from the thunder heads (not dunderheads) of the United States Bee-Keepers' Association. Bully! Now may there be no let-up to the cyclone till the bad boys are all in the cyclone-cellar—substantial and reticulated irons on the cellar windows.

COGITATOR.

GEORGE W. YORK, Editor.

PUBLISHED WEEKLY BY

GEORGE W. YORK & COMPANY,

118 Michigan St., Chicago, Ill.

ONE DOLLAR A YEAR.

SAMPLE COPY FREE.

[Entered at the Post-Office at Chicago as Second-Class Mail Matter.]

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39. AUGUST 3, 1899. NO. 31.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Marketing the Honey Crop will soon be a subject in which at least some bee-keepers will be interested. We would be glad to publish the experience of those who have really been successful in the line indicated in the home market. While everybody cannot be expert salesmen, still there are many good plans that no doubt could be used by almost anybody. The question is: How to sell the honey crop to the best advantage in the home market?

Removing Granulated Honey from Combs. Mr. John Kedrick gives the following method in the Canadian Bee Journal:

First take the cappings, after the honey has been drained out, and put them into a tub of lukewarm water and allow them to remain there for 24 hours or longer, then squeeze the cappings from the liquid. This liquid will be ready for use in the course of six months.

Then uncap the comb and place it in the liquid. Allow it to remain there for 12 or 24 hours, according to the strength of the liquid. Your comb will come out perfectly clean, without being injured. Old comb may be cleaned in the same way.

This liquid for cleaning the comb may be formed in another way, *i. e.*, in a gallon of water put about a pound of honey, and let it stand for some time. The length of time would vary according to the temperature of the place. If kept in a warm place it would be ready for use sooner than if left in a cool place.

After trying about every method, I have proved the above to be a great success.

The Honey Prospects in this (Cook) county have been good for the present season. Last Saturday (July 22) we took a bicycle ride among several of the bee-keepers within a few miles of our home, and found the bees were just rolling in the honey from sweet clover. And there are miles and miles of this wonderful honey-yielder in this county—seas and seas of the fragrant white bloom.

Among the apiaries visited were two of those owned by Mr. L. Kreutzinger, and that of Mr. H. S. Jones. Mr. K. has three bee-yards this season, in which are a total of 200 colonies. Some of the hives had four and five supers on them, many of the supers being ready to empty. He runs his apiaries entirely for comb honey, as does Mr. Jones also.

The four apiaries referred to are all surrounded with a great expanse of sweet clover, and should yield a bountiful harvest.

We believe Mr. Kreutzinger is the largest bee-keeper in this county. We presume he aspires to equal Dr. Miller, both in number of colonies and amount of comb honey produced (when the Doctor has a good crop). But we are inclined to think that Mr. K. did not make expenses during the past two years. But this year may help him out.

An Apiarian Picture Wanted. The editor of *Gleanings in Bee-Culture* offers \$10 for a satisfactory picture of "a young lady of prepossessing appearance, becomingly dressed, holding a swarm of bees on a limb she has just cut from a tree," and stipulates that she must be an unconscious beauty. Rather hard requirements! If she is appropriately dressed for bee-work, she will hardly be dressed in a very becoming manner, and if she can "have about her an unconscious air of ease and grace" when posing for a \$10 picture to be admired by all the readers of "A B C of Bee-Culture" well, perhaps there are some angels keeping bees.

We notice further that Editor Root says all that will be put below the picture will be, "A Good Catch"—not even the name of the charming young lady. Now, that's real mean! Many a young fellow will wonder why her full name and address is omitted if she is "A Good Catch"—presuming that the "Good Catch" may refer both to the winsome young lady and to the swarm of bees she is holding.

Get and Keep Up-to-Date. On page 468 of last week's number, Rev. L. J. Templin gave quite a sermon along the line of keeping up with the present progressive times. It will repay a careful reading even if you don't agree with all he says. We need occasionally to have recounted the many onward steps in our advancing civilization, lest we fail to note the rate of speed at which the world about us is moving, and we be left far in the rear.

Right in line with Mr. Templin's suggestions are the following, written by Editor Hutchinson in the July Bee-Keepers' Review, to which we invite attention:

CATCH THE SPIRIT OF THE TIMES.

Perhaps I am a little peculiar. I am quite given to following observation with speculation, theorizing and moralizing—to the drawing of lessons from very small circumstances. If a man comes into this town and starts in some business that is really overdone, and actually proceeds to take business right away from men who have been here for years, I am interested in knowing exactly *how* he did it. I want to get right down to the root and foundation, to discover the *principle* upon which he succeeded. If a man fails in business, especially one who has been apparently successful for many years, I am interested in knowing *why* he failed. In such cases there is almost always something wrong. I do not mean wicked, but not managed as it ought to have been. The causes of failures are numerous, and the one that leads to a particular failure is sometimes the

least suspected by the unfortunate man who is making the mistake. Some merchants have failed from employing cheap, inefficient help, under the mistaken idea that they were practicing economy. Others have greatly assisted their success by an opposite course. Some have failed from a lack of advertising of the right kind. Others have succeeded because of their excellent advertising methods. Others have failed because they did not keep up with the times. Their methods were all right for 30 years ago, but not appropriate for this age of steam and electricity. The time was when a man could sit in his office and wait for business to come to him. That day has past. Now he must go after the business—and hustle, too, while he is about it.

A new merchant comes into a town where the merchants are of the old class; he renovates the store from top to bottom, outside and inside; uses paper and paint and plate glass; makes a handsome display in his windows; changes this display quite often; puts in a telephone; has a nice delivery wagon; uses column after column, perhaps page after page, in the local paper; in short, leaves no stone unturned to boom his business; if his other methods of business are correct, he gets the trade, and men who have been in business for years, but have been in a rut, so to speak, will go down if anybody goes down.

I was quite interested in the way that Mr. Davenport sold his honey at a good price by advertising it in the local papers. This is an illustration of the advantages that may be gained by catching the spirit of the times. A merchant in a small town would find his dollars well spent if he would make a visit to the stores in some large city—simply that he might catch the spirit of the times. I do not mean that he could profitably put into practice all of the methods that he would see, but what he would see would help him to get out of a rut and into more modern and more profitable ways of doing business.

The way of doing things makes such a vast difference in the success or failure of any undertaking. I saw an illustration yesterday right from my office window. A man came along selling strawberries. He sat up straight on his wagon seat and bawled "s-t-r-a-w-berries." I saw one woman come out and buy some berries. A short time afterward two women came along selling berries. One woman drove the horse, and the other took a box of berries in her hand and called at the door of each house and showed her berries. There was scarcely a house at which she failed to make a sale.

If the manufacturer of some line of apiarian goods, whose goods are of the very best quality, would go at it in the right way, he could have the lead in the trade in that line of goods. The goods would have to be advertised in a telling, striking, unique manner. Some commission man in Chicago might receive the lion's share of the consignments of honey if he would advertise himself and his business in the right way. The same might be said of a commission man in New York, or any city for that matter. The trouble is, that so many of us are inclined to keep along in the same old way, instead of striking out and catching the spirit of the times.

Bee-keepers ought to read all of the journals, visit other bee-keepers, and attend conventions. They, as well as others, need to catch the spirit of the times.

Again the Spelling Reform.—Stenog touches on the Bee-Keepers' Review in the following paragraph, which we take from Gleanings in Bee-Culture for July 1:

Mr. Hutchinson is inclined to adhere in the main to the common spelling. He says: "So long as a system is radically wrong, we gain very little by tinkering with minor results." Further down he says, touching the fashions, "Girls' plaid shirt-waists must be laid aside for stripped ones." "Stripped"—how so, Mr. H.?

Don't you see, Stenog, that if Mr. Hutchinson followed the reformed spelling, such mistakes would be less likely to occur? If *stripped* were printed instead of *striped*, it would be corrected to *stript*, and then the error would come to the surface. Better climb in the band-wagon and come along, Stenog. To be sure, you have a big lot of prejudice, but then you have a bigger lot of hard sense, and it is only a question of time when the sense will overcome the prejudice. And you would be of very much assistance. Better come along now.

As to Mr. Hutchinson's argument, if argument it be

called—"So long as a system is radically wrong, we gain very little by tinkering with minor results"—there would be a good deal in that if it were generally admitted that the present system of spelling is radically wrong. The trouble is that so many think it radically right. Tinker some of the "minor" defects, and get the public used to it, so that the system will not be considered so sacredly perfect, and then the way will be easier to make radical changes.

MR. T. F. BINGHAM, of Clare Co., Mich., the big bee-smoker man, wrote us July 14: "Bees have done fairly, and are still doing a little."

MR. J. T. CALVERT, business manager of the A. I. Root Co., spent Friday, July 21, with us. He was returning from his annual trip among some of the Wisconsin and Michigan bee-supply manufacturers and dealers. Mr. Calvert was looking and feeling fine physically, showing that he hadn't been overworked in handling the bee-supply business this year.

MR. E. W. HAAG is the successor to Mr. Theodore Bender, of Canton, Ohio, in the latter's queen-business. We had the pleasure of meeting Mr. Haag at the Buffalo convention—in fact, he was one of the six or eight of us that "cotted" one or two nights in the same room. Mr. Bender will still continue to handle bee-supplies as heretofore. Mr. Haag's advertisement will be found in our advertising columns. We wish him every success, as we believe he fully deserves.

EDITOR H. E. HILL is in Florida, where he had an apiary three years ago, near the Indian River narrows. He gives a fine view of his apiary. The hives seem right on the brink of a large body of water, on which is a skiff. The picture is a tempting one, and makes one wish to go to Florida. On the St. Lucie River Mr. Hill extracted, barreled, and shipt 3,500 pounds of palmetto honey from 65 colonies in two weeks. When that failed he moved to Miami in the sailboat, and then to Stuart, making a cruise of 300 miles. One morning they were just ready for breakfast when an overhanging limb swept the table bare, throwing the viands to Neptune.—Gleanings in Bee-Culture.

MR. G. M. DOOLITTLE, in the Progressive Bee-Keeper, speaks thus about writing for the bee-papers:

"As the writers of the past were willing to shed light on our apicultural pathway, we would be ungrateful children indeed were we not willing to hand down that light to others, together with all of the accumulated light that we may have been able to gather as we have journeyed up the mount of apiculture. Oh! how much we owe to those who have preceded us, and yet how often we are selfish enough to hug the whole unto ourselves and keep all we may get and all we may produce within ourselves, claiming that we have a *perfect right* to all we can secure for ourselves. Having received, there is a *debt* hanging on every one thus receiving, to pay that debt with interest, to all who are about us, and in the paying comes far greater happiness than in the receiving. And this is the reason why I write, often when weary and greatly fatigued, when the couch looks far more inviting than the paper and thoughts which I am about to convey, but I thank God that duty calls louder for me to pay my *debts* than does the ease of the couch, especially if my 'scribbling' is of help to any one. Only as all unite in giving their mite to the common good, can apiculture reach the high table-grounds at the top of the perfected summit."

We might add for Mr. Doolittle's encouragement, that the writings of no other of our contributors are more highly valued than are his. So he can rest assured that his work is duly appreciated by many thousands who read the American bee-papers all over this country and others.

Odor and Color Make Bees Sting, says M. H. Mendleson, in *Gleanings in Bee-Culture*. It is generally believed that certain odors irritate bees, but some dispute that color has any effect. Mr. Mendleson says he buys light, odorless clothes and has no trouble. A gray and a brown horse of his pasture off the grass among the bees, and the brown is often stung at a distance from the hives, while the gray is never stung except when switching the flies.

Does Loss of Sting Cause Death? is a question discussed in *Gleanings in Bee-Culture*, by G. M. Doolittle. Among other things, he says he once mailed a queen on an eight days' journey, putting in with her a worker that had left its sting in his finger, and the customer wrote him that every worker in the cage was alive. Editor Root says that he has several times confined in cages bees deprived of their stings, and they lived two or three weeks, or as long as they would have lived with their stings.

Two Queens in a Hive. An unusual case was this: June 26 I found in a nucleus a young queen with her wings gnawed entirely away. Directly I found on the same comb a young queen with perfect wings. The two met and had a little conference, but did not seem very hostile. Next day both were present; the 28th I saw the winged one; 29th, the wingless one; July 3, the winged one. So both were there together at least three days, and whether the wingless one is still there I don't know. *Gleanings in Bee-Culture*.

Crimson Clover. J. W. Allison, in the *National Stockman*, says the chief value of crimson clover is as a soil renovator, for which purpose he considers it superior to any other plant grown. August sowing made a failure, but earlier sowing succeeded. It makes fair hay, but is very hard to cure. It yields 6½ bushels of seed per acre. Sow from July 15 to 20, cover the seed one to three inches—no danger of getting it too deep—then it will make such a good growth by winter that if it does winter-kill you still get big pay for it as a fertilizer.

Shade for Bee-Hives.—Editor Root probably voices the general sentiment in *Gleanings in Bee-Culture*, when he advocates the shade of trees as the best. He has a decided dislike for grapevines, nicely trellised up, because their care is laborious, and because the rapidly growing shoots get in the way of the operator. Near almost every farmhouse stands an orchard, and there, Mr. Root thinks, is the proper place for an apiary. A hive can be so placed under a tree that it is fully shaded during the heat of the day, the sun shining upon it early in the forenoon and late in the afternoon, when the heat is milder.

Izal for Foul Brood. While drugs for the cure of foul brood are not looked upon with very great favor in this country, the case seems to be somewhat different across the water. The editor of *Bee-Chat*, especially, is enthusiastic as to the use of izal. He says:

"It is a fatal error for our scientists to preach the indestructible nature of foul brood spores, in that they readily germinate in the living temperature of the hive, they are easily disposed of in detail, and, therefore, with a little assistance, the strong colony will have no more of them. Only cause the spores to germinate where the said germs find no means of continued propagation and there is an end of them. We have proved conclusively, a strong colony will, under certain conditions, give no resting-place to spores or germs; how much more so with judicious assistance!"

J. O. Buntler reports in the same journal that by taking the disease in its early stages he is entirely successful with the following mode of treatment:

"If I suspect a hive, I take out the brood-combs, and find in its early stages the disease exhibited here and there in two or three cells by a yellow-looking grub or a dark-sunken-looking covered cell, or even one pierced with small, irregular openings; directly I see this, all such cells, if possible, are cleared out (I use the end of a match) and sealed cells are broken open; when this is done, the bees clear

them out, but if not they often leave them sealed up, and give rise to a possible source of infection hereafter. I then see that the naphthaline supply in the hive is a liberal one—in fact that the hive on opening it smells of the naphthaline. I then feed regularly, and in as great a quantity as they can take down, with syrup medicated either with izal or naphthol beta. Directly the bees take this down, there is a noticeable alteration in their behavior, they become more energetic, and a week after the commencement of this treatment, on opening the hive, you will notice the foul-broody cells cleaned out, and healthy brood in its various stages all around the infected area. Again, any more cells which appear infected are opened up and cleaned out, and the feeding, etc., is kept up until the hive has a clean bill of health. If the bees will not take down the medicated food, I force it into the cells with a syringe."

Alsike Clover will yield honey for six weeks, with frequent rains, and a heavy flow for a full month when all conditions are favorable, says F. A. Snell, in *Gleanings in Bee-Culture*. It may be cut for hay when just nicely in bloom, and thus made to yield honey later. A strong point in favor of Alsike is its hardness. Mr. Snell has never known it to winter-kill, and it has repeatedly wintered well when red clover has killed out entirely. If not wanted for seed, it is well to sow a little timothy with it, as it stands up better. The length of stalk is usually two to three feet—sometimes on rich land four feet.

Powdered Sugar for Queen-Cage Candy. "Cogitator" says, in the *American Bee Journal*, that if powdered sugar is almost always largely cornstarch, it has an important bearing on the provisioning of queens for journey. Worth thinking about. [We have used what is called confectioners' and powdered sugar; but the former contains starch, without a doubt, and it is liable to kill bees and queens in queen-cages provisioned with candy made with it. We have, during the last few years, ordered powdered sugar, and specified that it should contain absolutely no starch. Since we have discovered that confectioners' sugar contains starch, and have used nothing but the powdered sugar without the starch, we have had very much better success in sending queens long distances. With powdered-sugar candy we provision long-distance cages, sending them to Italy, and then have them returned with queens and bees. We have had several shipments by mail, of a dozen each, with scarcely the loss of a queen.—Ed.] *Gleanings in Bee-Culture*.

A Simple Solar Wax-Extractor, for those who have not more than 20 colonies, is given in the *British Bee Journal*, by Walter Reid, as follows:

"The first requisite is a wash-hand basin, preferably white, and as round as possible inside—not flat-bottomed. Into this is placed an enamelled colander about six inches in diameter, with a small piece of muslin to cover the holes and strain the melted wax. Upon the basin is placed a sheet of glass, and the extractor is ready for use. For the colander a small pudding-basin may be substituted, with a piece of muslin tied over the top. The pieces of comb are placed on the muslin, and the wax will be found in a cake at the bottom of the basin. In order to secure the highest efficiency, the outer basin may be placed in a box full of dry sawdust, or, better still, cork-dust. Cork-dust prevents the radiation of heat so effectually that at 8 p.m. I have found the wax of the consistency of butter, and could easily remove it with a spoon. Instead of one piece of glass a double thickness may be used, or a piece of old plate-glass. The temperature in this or any other form of solar extractor can be considerably raised by placing a sheet of glass almost vertically upon the glass cover in such a position that the rays of the sun are reflected down into the apparatus. Careful thermometric measurements have shown that the temperature may be augmented more than 50 degrees Fahrenheit by this means.

"Before placing the comb into the extractor it is worth while to cut it up and wash it in cold water. This gets rid of much of the pollen, which otherwise absorbs a considerable proportion of wax. Those who wish to obtain a maximum yield, especially in the case of old combs, should soak the crushed combs for 24 hours in cold water; then boil for a few minutes, and extract the crude cake of wax in the solar extractor."

The Premiums offered on page 474 are well worth working for. Look at them.

Root's Column

GLEANINGS AT REDUCED RATES....

We do not need to tell you about our journal, for it will speak for itself; but as an extra inducement we make the following low offers:

Offer No. A.

For 25 cents we will send GLEANINGS IN BEE-CULTURE from the time your subscription is received until January, 1900. If you send in your order promptly you will get 6 months for only 25 cents.

Offer No. B.

For \$1.00 we will send an untested Italian Queen worth 75 cts. and GLEANINGS IN BEE-CULTURE one year.

Offer No. C.

For \$1.00 we will send GLEANINGS IN BEE-CULTURE the rest of this year and all of next year, that is, from the time your subscription is received until January, 1901. The sooner you take advantage of this offer, the more numbers you will receive.

Offer No. D.

For 50 cents we will send GLEANINGS IN BEE-CULTURE 6 months beginning July 1 and Vol. I of Gleanings. This is for the year 1873. There are many interesting things. There are 12 articles on "Starting an Apiary," and while some of these may not be practical now, there is much valuable information and it gives a good idea of bee-keeping at that time. Our supply is limited and of course we cannot continue this offer long.

Old as well as new subscribers may take advantage of these offers, but all arrearages on back subscriptions must first be paid at \$1.00 per year.

ADDRESS

**THE A. I. ROOT CO.,
MEDINA, OHIO.**

In the multitude of counsellors there is safety. Prov. 11-14.

Water in the Apiary How to Supply.

Query 99. Is water in the apiary for the use of the bees a necessary factor? If so, please give one or more methods for supplying it. FRANK.

G. M. Doolittle—Yes. Small streams and ponds near by give me all the bees require.

J. M. Hambaugh—Yes, or thereabouts. A long narrow box with a float to prevent drowning.

R. C. Aikin—I think not, but I frequently give water. I have a big galvanized pan with stones in it.

Dr. C. C. Miller—It's a good thing. A six gallon crock with sticks of firewood and filled up with water.

Prof. A. J. Cook—Yes, unless it can be secured hard by. In a dish with slatted float, or covered with chips.

Dr. J. P. H. Brown—It is a very necessary factor when breeding. Shallow wooden troughs placed about the apiary.

W. G. Larrabee—Of course, water is necessary, but in most locations it can be had without being supplied by artificial means.

P. H. Elwood—Locate your bees near the water. If you cannot, then take the water to them. I have never found the latter necessary with me.

Chas. Dadant & Son—Yes, but they usually find it, if only from the dew. Supply an inverted jug on a dish covered with a piece of woolen cloth.

E. France—That would depend upon the distance to a supply outside of the yard. A shallow tub, or box with floats in it, is a good water arrangement.

O. O. Poppleton—I have never yet kept bees where they couldn't get what fresh water they wanted from natural sources. I think it is necessary they should have fresh water.

Mrs. L. Harrison—It is. I place tubs such as butter comes in, with a cloth hanging in and out of it. One with water a little brackish; a spoonful of salt to a pail of water.

G. W. Demaree—If there are open pools or ponds of water brooks or open springs within a half-mile of the apiary it would be a waste of time to water bees by artificial means.

J. E. Pond—I have never so considered it. A good plan for watering is to place shallow troughs in the yard filled with chips or cut straw, on which the bees can rest while taking water from them.

C. H. Dibbern—Yes, it is very important to have water conveniently near the apiary. A beer-keg with a small hole near the bottom, with a quill partly plugged up, allowing the water to drip on a gunny sack, is good.

Eugene Secor—Water in or near the apiary is desirable. If none is near I would supply it. A Mason fruit-jar, or similar vessel, a pine board and a jack-knife are all the capital needed to make an excellent drinking fountain.

Emerson T. Abbott—I think it is. I let my bees drink out of the chicken trough, which is a wooden box with slats over it to keep the chickens from getting into the water. By the way, do you give your chickens plenty of water?

Rev. M. Mahin—Bees, at certain seasons, must have water that the nectar they gather does not supply. If there is not a supply within easy reach, it ought to be supplied. I supply it by filling open-mouthed

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |
|-----------------------|-----|--------|--------|--------|
| Sweet Clover, melilot | 60c | \$1.00 | \$2.25 | \$4.00 |

jars or cans with water and inverting them in flower-pot saucers, putting something under one edge of the jar to raise it up so that air can get in and water get out.

"Mrs. J. M. Null—Yes. Practical methods which are at once inexpensive and efficient are constantly found in the bee-papers. Common-sense and necessity will discover a feasible method. "Necessity is the mother of invention."

C. Davenport—Bees certainly require a large amount of water for brood-rearing, and if there is none near, it would be a great help to them to have it supplied near the yard. Throw a quantity of clean corn-cobs in tubs or barrels, then pour in the water.

J. A. Stone—We think it is, and keep a tub (elevated three or four feet) with a little salt in the water, and the best plan we have tried to keep the bees from drowning is the one Mr. J. Q. Smith told us about—a cloth spread over the top and sagged to dip in the water.

Adrian Getaz—It is necessary that water should be within reach. One good way to provide it is to have a sheet-iron tray about three feet wide and long, and four inches deep. Fill it with moss, and put a bucket of water in it occasionally. The moss furnishes the bees a foothold.

D. W. Heise—If there is no water close to the apiary I would consider it of benefit in early spring. Take planks and bore them full of holes, say one inch deep, with a two or three inch auger, making communications from one hole to the other. This is very cheap, and answers very well.

E. Whitcomb—As necessary as to furnish water to stock in pasture. Use chicken fountains, or jar or can inverted over a block in which grooves have been cut not quite to the outside. Try them and get rid of spring dwindling. Slightly sweeten the water for a day or two to entice the bees.

J. A. Green—Yes. As water has always been plentiful in or near my apiaries, I have had no experience with artificial methods. Their preference is for a place where they can sip water without any danger of getting wet, such as the moist soil or gravel along the edge of a stream or pond.

Mrs. A. J. Barber—Yes. A large trough with coarse hay or straw thrown in loosely several inches deep, and then water poured in, is good. The straw, if not too fine, enables the bees to get water and crawl out without getting wet. A leaky five-gallon can to drip on boards is good, but we like the trough best.

R. L. Taylor—Water is necessary for the bees, but they get it from the margins of ponds, marshes and streams. If none of these is convenient, water may be supplied near by in any kind of vessels, furnishing each with plenty of floats of shingles, pieces of boards, etc., to enable the bees to get to the water without danger of falling into it.

A. F. Brown—I have never been situated where there was a total absence of water. Being near the sea-coast (Florida), if my bees cannot get fresh water, they go to the beach by thousands and get salt water. From their anxiety to obtain it I should say it was very essential. In places where it is absent otherwise, they obtain it largely from the dew of night.

E. S. Lovesy—It is, and two of the best methods for supplying it that I know of are: First, take a good-sized pan and fill it with moderately small cobble rocks, then nearly fill it with water. Second, take a keg or small barrel, bore holes in it and stuff rags in the holes just tight enough so the water will seep thru and keep the rags wet. Keep the keg supplied with water.

Dr. A. B. Mason—For the best results it is. In less than one day about the middle of April last, 60 colonies of bees took a ten-quart pail of water that had been sweetened just enough with honey so it could be tasted as sweetened. On other days they would take from two to three quarts of water with no honey in, but in each case some cappings without honey were put on the water for the bees to alight on. A

stone crock or jar is better than a wooden vessel. Some use and prefer a glass or other receptacle turned upside down on a board with creases cut in the board, where the bees can sip the water.

Good Honey Crop Expected.

I see by the reports of different bee-keepers that the prospects are very poor for a honey crop this year. Here in southeastern Kansas the bees have had a continuous honey-flow from the time the fruit blossomed. They commenced to swarm the first of May, and swarmed until July 15. I had 17 colonies, spring count, had 17 swarms to issue. I doubled four (making 13 new swarms) and bought two, making 32 colonies now. The honey-flow is good, and the bees are working in the sections. The prospects are that there will be a good honey crop this year in this section of country. The most of the bees are kept in boxes and kegs. It is very wet here now. Some of the grain has been threshed, and some is in the shock and somewhat damaged by the wet weather. The corn crop promises the largest for several years. L. WAYMAN.
Labette Co., Kans., July 22.

Will Not Overstock the Market.

Western Pennsylvania will not overstock the honey market this year. Here is another to thank you for publishing Doolittle's excellent article on price of honey. W. J. DAVIS, 1ST.
Warren Co., Pa., July 21.

Discouraging Season.

This season is very discouraging to me, as I lost nearly half of my bees last winter. I have not a pound of honey and no increase. Some of my neighbors had some swarms, and lots of honey. I have been keeping bees 10 years, and have beaten all my neighbors every year in honey and increase, until this year. My bees are blacks and hybrids. I lost what Italians I had last winter. Where I live is the coldest place in this country, and those of my bees that weren't frozen to death were chilled. Some of my best queens that were reared last year and proved to be hustlers, are no good at all this year. Not only my bees froze, but some of my farm stock. It is bad luck with me about my bees. W. W. GARDNER.
Fayette Co., Ala., July 17.

Poor Prospects for Honey.

We had a very windy, cold April, and a freeze May 22. March was very mild—fruit, willow and cottonwood all bloomed in March—and bees built up and began to swarm by April, when it turned cold and froze everything, and continued cold and

windy until May 22 Bees became very weak, and a great many died that did not have proper attention.

The mesquite was almost an entire failure for the first time in 10 years. The cause of its failure was the cold spring. Also the alfalfa was a failure until now, and bees are storing some honey from it. The sunflower is good, and another yellow flower that is good will last until November. Its name I do not know; I call it the "Alkali honey-plant."

B. Palam had 194 colonies, spring count, has had only 15 swarms, and has taken only 672 pounds of section honey up to date. He runs his bees in two apiaries about seven miles apart. Other apiaries have done about the same as Mr. Palam's.

I happened in a store in our little village a few days ago, and saw a super of honey on the counter. I lookt in it, and to my surprise it was filled with 1/2 depth Langstroth frames of nice white honey, but was broken in a few places, and the honey was running out. It had no cover on it except a newspaper. It was covered with flies. The merchant said, "I don't want any more honey; it is running over everything, and is only good to draw flies." I don't know what a man wants to put honey on the market for in that shape, except to disgust the merchant and ruin the price of a good article. W. D. JEFFERSON.

Graham Co., Ariz, July 12.

Clover Almost Nectarless.

Basswood was slighted by bees, and there was not much honey in white clover this year. Last year I wanted surplus honey and no swarms; I got honey-dew but no swarms. This year I wanted surplus and swarms; only about half of my colonies swarmed, and I will get hardly any honey from the swarms this year, but about all my surplus will be from colonies that swarmed and those that did not; something unusual for me. I am shipping my honey this year, and prices are good—20 cents per pound.

I think honey-dew killed the bees last winter. I lost about 1/4 of mine.

Richland Co., O., July 24. S. POLAND.

Very Short Honey Season.

I have taken 3,000 pounds of fine, white clover honey. The honey season is very short. Clover is still in bloom, but no honey since July 10. There was clover enough to give 100 pounds per colony, but it did not "give down" till late. J. S. C. STEWART.

Nodaway Co., Mo. July 24.

Hardly Any Honey.

We are in the midst of barley harvest, but 3/4 of it was killed by last week's rains, and hot sun at midday. Most of it will do only for feed. I have about 100 acres of it. Wheat and oats are all right as yet, and will be ripe in about a week. There is hardly any honey. C. THELMANN.

Wabasha Co., Minn., July 24.

Brood Died as it Hatcht.

My apiaries did well until after heavy rains in June, then all the brood as hatcht died with something like paralysis within 24 hours. Being a "tenderfoot" in Texas, it was a new thing in my experience, but on inquiry I found it the same with others. Some said sour pollen caused it; others, poisoned honey, etc.

After close examination I found mine had no pollen, so I went to feeding rye-flour and oat-meal, dampened in straight sun-extracted honey. They had quit capping, and the brood was dying in the comb. They have now quit dying, are capping brood, and going ahead, but I suffered severely from loss, as there is no hive force to assist the field-force, and a small white-brush flow on, still they bring no pollen to amount to anything. This is no farming country, but the bees have three acres of corn and cane

at home, and a large field of corn within about one mile.

I have had no means to find out to what extent the trouble referred to has run, only right in this neighborhood, running north on the Sabinal river. From my experience so far I think it was caused by starvation from want of pollen, as many of mine had 30 to 50 pounds of honey each in their supers.

J. M. McCURDY,
Uvalde Co., Texas, July 21.

Getting No Honey.

We are not going to get any honey at all here this year. It has been so dry, and clover had no honey in it. Only about one-fifth of the colonies have swarmed, as they are hardly getting enough to live on. Unless golden-rod yields well we shall have to feed for winter stores. W. E. VIRGIN,
Merrimack Co., N. H., July 17.

A Good Wagon

begins with good wheels. Unless the wheels are good the wagon is a failure. IF YOU BUY THE ELECTRIC STEEL WHEEL made to fit any wagon—your wagon will always have good wheels. Can't dry out or rot. No loose tires. Any height, any width tire Catalog free. ELECTRIC WHEEL CO., BOX 16 QUINCY, ILL.

HONEY AND BEESWAX
MARKET QUOTATIONS.

CHICAGO, July 19.—A little comb honey is coming and the best white in pound sections brings 13 cents; some of it is not properly sealed and leaks from those few uncap cells sufficiently to stain the cases and thus detract from its value. Amber grades, 10 1/2 cents, and dark, 7 1/2 cents. Extracted, white, 7 1/2 cents. Amber, 6 1/2 cents. Beeswax, 26 1/2 cents, and sells on arrival. R. A. BURNETT & Co.

KANSAS CITY, July 7.—A small shipment of new comb honey on the market is selling at 14 1/2 cts. Good demand. C. C. CLEMONS & Co.

NEW YORK, June 9.—Demand good for extracted honey, all kinds, and same finds ready sale at the following prices: Fancy, 7 1/2 cts; choice, 6 1/2 cts; fair, 5 1/2 cts; common, 5 1/4 cts per gallon. Some demand for comb honey at from 11 1/2 cts for white, and 9 1/2 cts for amber. No more demand for dark. Beeswax dull at from 25 1/2 to 27 cts per pound, according to quality. HILDRETH & SEGELKEN.

SAN FRANCISCO, July 12.—White comb, 10 1/2 cts; amber, 7 1/2 cts. Extracted, white, 7 1/2 cts; light amber, 6 1/2 cts. Beeswax, 26 1/2 to 27 cts.

Only moderate quantities are arriving of either comb or extracted, with no prospect of the market being heavily burdened with offerings any time this season. Business is mostly of a jobbing character, and for such transactions the market is firm at the quotations. Some extracted of superior quality is arriving from Monterey County.

CLEVELAND, July 22.—Fancy white, 13 1/2 cts; No. 1 white, 12 1/2 cts; A No. 1 amber, 10 1/2 cts; No. 2 amber, 9 1/2 cts; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

BOSTON, May 17.—Fancy white, 12 1/2 to 13c; A No. 1, 11 1/2 cts; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7 1/2 cts; light amber, 6 1/2 cts. Beeswax, 27 1/2 to 28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is liked at this season of the year. BLAKE, SCOTT & LEE.

BUFFALO, May 5.—The season for honey is about closed. Some extra fancy white would sell at 11 1/2 cts; some very poor selling at 6 1/2 cts, and dull. No more business in honey before the opening of the ensuing season. BATTERSON & Co.

OMAHA, July 18.—Altho first receipts of new crop Southern honey were recorded early in June, there has not been any regularity about them since. A straggling lot of comb turns up now and then, and when quality is choice to fancy, is eagerly picked up at 14 1/2 to 15c. A little lot of 1898 crop was received a few days ago and went at 13 cents, quality not above choice. For extracted there is not such an urgent demand. Still, 7 1/2 to 8c would be obtainable in a small way. The heavy buyers will hold back until later in the season, expecting to purchase on about the same basis of values as last year. Early shipments of all the comb that can be gotten out is certainly advisable; there will not be any chance of holding out with present quotations after the first demand is satisfied. PEYCKE BROS.

DETROIT, July 15.—No old honey to quote, and no new offered. Prices are liable to rule higher as crop is short. The abundance of rain will no doubt help the crop of fall honey. Beeswax in good supply at 23 1/2 to 24c. M. H. HUNT & SON.

CONTRIBUTED ARTICLES

A Useful Hive-Tent and Comb-Rack.

BY E. FRANCE.

THE hive-tent is 10 feet square, 7 feet high, with covering made of cheese-cloth. The top is made separate from the sides, and the sides and top are fastened together with snaps and rings, leaving an open space of two inches all around the top to let out bees that leave the hives that we are at work with. The sides come down tight to the ground.

To get in and out of the tent, raise one side high enough to go under by stooping, then drop the side down again.

We use the tent in the spring-time to clip queens, when fruit-trees and dandelions are in blossom, or at any time when the bees will rob, when there is no honey coming in.

To make the frame: The corner posts are made by ripping a 2x4 pine; dress the pieces smooth, then dress off the corners, leaving them 8 square, except 6 inches at the top and a foot at the bottom, which leave square. Bore a half-inch hole in the center of the top of the post down 6 inches, and put a staple near the top to tie the brace-ropes; put another staple near the bottom for the same purpose to hold the brace-ropes. We use a 3/8-inch rope. Now we want five pieces of good pine, 2 inches wide and 7/8 thick, to go around the top—one of them across the middle to hold up the center of the cover. Bore a half-inch hole thru all of the pieces 1 1/4 inches from the ends; get six 3/4-inch bolts 6 inches long. Lay the 2-inch strips on top of the posts, and drop in thru the strips and down into the posts at each corner, one of the bolts. For the center strip we have a half-inch hole in the middle of two of the side-strips, with a bolt in each end.

We must fasten the tent to the ground. Get four pieces of 3/8-inch round iron 22 inches long; bend one end at right angles 4 inches, and sharpen the other end. Now we want two staples for each post—one about two inches up from the bottom, the other one above it about 6 inches. Leave the staples out far enough to drop in one of the stake-pins, then put your foot on the top of the pin and push it into the ground. Those pins are all that we want to hold the tent, with those brace-ropes inside. Put on the cover and it is ready for work.

The illustration shows the tent with one corner hitched up on the top of the post. A pretty big hive-tent, but it is none too big for our use. We use a large hive, that holds four colonies, and with four men and our traps to work with, the tent is about right. We used to use an 8-foot tent, but it was too small.

To move the tent, one man at each corner, pull up the pins, take hold of the post and lift it up and walk off with it to where it is wanted; set it down, put one foot on the pin, push it into the ground, and we are ready for work.

The comb-rack is built of 2x4 inch upright timbers, and 1x4 inch boards on the sides. The picture shows the comb-rack to store extracting-combs in during winter. Several Wisconsin bee-keepers that save their combs in this way are able to produce tons of choice honey each in a single season.

Grant Co., Wis.

[See illustration of the comb-rack on next page.—Ed.]

Mr. E. France and Hive-Tent.

Barrels as a Honey-Package. Once More.

BY C. P. DADANT.

I SEE that Cogitator does not at all like honey-barrels, and so pokes fun at me for taking the part of the discarded vessel. (See page 453.) But I do not believe that Cogitator has as much experience with honey-packages as I have, setting aside all modesty, of which I have no great

store anyway. I did not write about barrels theoretically. In fact, I don't write in the bee-papers theoretically concerning any point. What I give is from experience of 30 years of daily practice with bees, or honey, or bee-goods. So if you differ from me it is simply because you take matters from another stand-point; but the acquired experience of years cannot be done away with by a few jokes, or a sneer, and even tho I may not be approved by the mass of the readers, I will stay with the assertions previously made by me, that altho tin-cans are a progress, and are very handy in a number of cases, still the old honey-barrel will remain, in many cases, a useful vessel.

Cogitator says that I did not explain how a "glue-coated" barrel could have its staves spread and closed again, and yet be proof against honey soaking as before. I did not think that it needed explaining, because I thought any one might try and see how it behaved. The glue fills up the crevices, and their spreading apart does not cause it to break away from those crevices, but it simply shuts together when they are brought together again, and the barrel *does not leak*. Facts, not fiction. The description that Cogitator gives of his trial at opening a barrel simply shows that he will do much better as a tinner than as a cooper.

I have put up honey in small receptacles, both from barrels and 60-pound cans, and when it comes to emptying the honey of five barrels, or of its equivalent in tin-cans—44 to 46 60-pound cans—give me the five barrels with all the fuss of taking out the heads and putting them in again, and with all the little do-funnies of the cooper that so much annoy Cogitator. The 45 tin-cans may be dried on the stove, sure enough the fact is, I have done it on some of them, but I got sick of it long before I got to the 45th can, and my five barrels did not leak as much as those dried-up cans when they happened to get a little too warm and the solder run off the joints. It is evident that Cogitator had only one can or two, and took his time, and had the stove just right—neither too cold nor too warm—and could give the steam its own time to get out of those cans thru the screw-cap opening.

A good many people succeed at one thing while others succeed at another, and we often pass by a very simple thing without seeing it. So it may be that my way is not the best, but I will tell you all the same how we do when we extract, and Cogitator, or some other man, can tell us of a better way.

You all know that when the honey first comes from the extractor, it is a little cloudy, containing chips of cappings, motes, and probably a few impurities from the hive. It is only after a few days that it gets bright and clear, or at least after a few hours. When we first extracted we had imagined that we could strain it clean at once by draining it thru a very fine sieve. But we soon got over that fancy. The very fine sieve got so stoped up that it would have taken all day to put in ten gallons. So it had to be put aside and an ordinary flour-sieve such as would stop only the large pieces was substituted. The first manufacturers of extractors labored under the same delusion, and we remember that all our early-made extractors were fitted with movable sieves inside of the can which had to be removed because they soon got so stoped up that the honey would not go thru them.

Now, when we put up our honey into barrels the honey settles, and in about two days, if we see fit, we can draw off all but about four gallons perfectly clear. The last four gallons are put in a separate vessel, and in a short time the top is skimmed off and our honey is all clean. If we were to use tin-cans first, last, and all the time, we should have to draw our honey first in a vessel where it would settle before we filled our cans, or we should have more or less skimmings in each can. That is another reason that I had not given before, for our preference of barrels to cans when the honey is first taken off. Of course, large tin vessels may be used instead of wood, and that is only a question of

cooper or tinner, but I cannot see how we could go to our out-apiaries with tin vessels and load and unload the crop with as much ease if we used large tin-cans to put the honey in until it settled, as with barrels.

Now another thing: I am ready to assert that there is more loss, on an average, with good tin vessels than with wooden ones, and I see that I have a helper in the same number of the American Bee Journal in which Cogitator's criticism appears. On page 458, Editor Hill is quoted as saying that he "has used a number of earloads of tin-cans as a honey-package, and has found the percentage of loss thru leakage greater than where barrels are used." Thanks, Mr. Hill, for this shoulder to the wheel.

If our tin-cans were always handled carefully there would be little danger, but honey is so heavy an article that the railroad folks are very often displeased when it becomes necessary to handle those boxes containing one or two 60-pound cans, and the result is they are dumpt around with very little ceremony. I have often known a can to become emptied because one of the boards of the box had become unnailed in rough handling, and the nail driven again, but, driven wrong at the next turn, had been brought in contact with the tin. These holes are worse than cracks in barrels.

Mr. Editor, pardon me for this long discussion of a subject which is already thoroly ventilated: I wanted to explain my reasons for supporting the use of honey-barrels, and for using them myself, for we are at it again, and the boys have this very day filled two barrels from our home-apiry.

I do not think barrels are an absolute necessity in an apiary, but they do very well as a temporary storing-vessel, and when honey is to be used for baking or for other manufacturing purposes the barrels are not to be discarded altogether, *even as a selling package*. Hancock Co., Ill.

Removing Honey by the Bee-Escape Plan.

BY F. A. SNELL.

WHEN honey is coming in slowly, or none being gathered at the time one desires to take off honey, the bee-escape is very useful or almost indispensable. Near, or after, the close of a honey-flow, bees are very much inclined to rob, so no honey should be exposed. A bee-escape is inserted in a board cleated to give the proper space, and this board or escape is placed under each super to be removed. It is so arranged that the bees can leave

France's Rack for Storing Combs.

the super, but cannot return. In doing this work the smoker is lighted, and with the hive-opener in hand and a few escape-boards we proceed.

The bees of the first hive to be worked with are given a few whiffs of smoke at the hive-entrance, as we do at all times before opening the hive. With the hive-opener we pry up the super to loosen it, and then lift it off, after giving the bees a few puffs of smoke, and place it one side. We then put the escape board over the brood-chamber, and place the super or supers over this. The bees finding they are shut in, and away from their queen and brood, search for a place of escape, which is thru the escape only.

All escapes are put on the hives having supers either for extracting or those used in getting comb honey, but we take one or the other in order. That is, the comb honey will all be taken off before beginning on the other, or *vice versa*. In from a few hours to a day the supers will be rid of bees, depending upon the weather and space above the escape-board.

The supers, when rid of bees, are lifted from the board and taken to the honey-room. The bees at this time should be treated to smoke and kept under control, as the hives are quite apt to be jarred when prying up the super. In this way a large amount of honey may be taken off so quietly that the bees are not aware of the fact, and no excitement or robbing caused.

The escape-boards may be removed as one removes the supers, the bees driven down, and the cover put on the hives, or the supers may all be first removed to the honey-room, and the boards later in the day. With this plan not a frame of honey need be handled in the bee-yard to tempt the industrious bees.

Before the invention of the bee-escape there was no way to take off honey without demoralizing the bees, unless one waited until cool weather had driven them from the surplus department late in the season. This work is much better done now during the warmer weather, when the bees handle to better advantage, and the work is then out of the way.

I have tried all the bee-escapes that have been brought out among bee-keepers, and have only found one among the number that worked well, and that is what we now use, as all others have been thrown away as useless.

At the time of a good honey-flow, either the shake-off or escape plan works well, as no robbing will then occur, anyway. Carroll Co., Ill.

Hunting Bees in Trees During a Honey-Flow.

A SHORT SYMPOSIUM.

IF L. J. Clark will go along streams of water he will find bees gathering water (if there are any bees in the vicinity); then watch the course they go, and it will not be much trouble to find them. DANIEL LOY, Preble Co., Ohio.

In answer to L. J. Clark (see page 445), in regard to hunting bees during the honey-flow, I would say, go where you have reason to think the bees are, and find them at work on water. When they leave the water they won't circle, but go straight to the tree. Generally they get water at the nearest point, so if you are a mile from tame bees you may rest assured they are wild. If you don't get the line the first time, wait and the bees will come back to the same place as soon as they can unload.

It is a very poor season here; 40 percent loss last winter, and very few swarms this season; small honey crop, and poor prospects for any more. H. L. CASE, Ontario Co., N. Y., July 14.

Referring to L. J. Clark's call about bee-hunting, I will try to explain to him about my methods. I have traced bees three miles, and have found them in trees.

First, take a box about the size of a cigar-box (a cigar-box will do); cut a hole in the bottom about an inch square, then place two wires thru the box about half way between the bottom and the top, and place the bait on the wire. Then take a glass for a lid, and put it on top of the box. Take the box, and when you see a bee on the blossom, place the hole in the box right over it, then it will go into the box, thinking it can go right up thru. When you have about a dozen in the box take it out in an open field, set it down quietly about four feet above the ground; watch thru the glass lid till they begin to work on the bait in the box, then lift the glass lid, which will leave them ready for their

home. Lie right down below the box, so that when the bee starts you can see her circle three or four times. Then she will make a straight line for her home.

The bait is some fresh honey, with about half fresh water with it; make it about half water, so it will be nice and thin, almost like water. To about half a pint of bait add about three drops of golden tincture or ether, and I will guarantee any bee to work on this bait in any time of the year. An empty comb is best to put the bait on. I would like to hear from Mr. Clark after giving this a trial.

Coshocton Co., Ohio.

SAMUEL VARNES.

I have read the letter of L. J. Clark, on page 445. I do not know whether I can help him any or not. Bees will sometimes work on honey in the afternoon, even when flowers are plenty. I think I would start them in the afternoon, and they would probably work back on the honey in the morning. If he uses comb honey in his boxes, as I understand from his letter, he might try instead an old brood-comb in his box, and use a little extracted honey diluted about one-third with water.

Bees will not work if caught from buckwheat in the morning; I do not know whether they will from white clover or not.

Oil of anise is generally used to call bees, but it is my opinion it is only of use to aid bees in finding the honey when coming back, by its strong odor. Never put oil of anise in the honey or in the box. Bees will leave immediately. I have found two bee-trees so far, and without hunting them, either.

I have caught five swarms in decoy hives set in the woods. Bees have not swarmed here this spring; it was so dry in April, May and June. I will guarantee I can catch 20 to 30 swarms of bees in any good year.

Dutchess Co., N. Y.

GEO. T. RECORD.

I will describe the way I hunt bees in New Hampshire.

First, take some strips of lumber 1 3/4 inches wide, about 5/16 thick, and make three boxes 2 3/4 inches wide, 3 3/4 long, nail a bottom on one. This will be the comb-box. Before nailing the other two together cut two grooves on the inside of each side-piece of the box, one groove near the top, and one near the bottom; then cut a piece of glass that will just fit into the top groove, when you nail the box together. When nailed, fit a thin wood slide in the bottom groove—these are the catching-boxes.

In the comb-box fit a piece of black brood-comb—the old black comb is the best, as it won't soften in the heat of the sun. Take some good granulated sugar and water, equal parts, mix well together, and fill the piece of comb in the comb-box. Get a very small vial of oil of anise, and now you are all ready to start.

Go where the bees are working on the flowers, set the comb-box on a stump or stake on anything that will be seen by the bees when they "come back." Don't set it too near the flowers (at this time of year). Then take one of the catching-boxes, draw the slide nearly out, take it in the right hand with glass side up; when you come up to a flower with a bee on it, put the left hand under the flower, bringing the box down over the bee, and the left hand up under at the same time; the bee seeing the light thru the glass will fly up against it at once, when you push in the slide, and you have the bee. Go to the comb-box, put the catching-box on top with the slide side down, then draw the slide, put your hand over the glass to darken it inside, and the bee nine times out of ten will at once begin to fill. You can look in the glass and see if she is loading up all right. If so, raise the catching-box gently, and take it off; then sit down and watch the bee go; also note the time, so as to estimate the distance they are from you.

Be sure to put a little oil of anise on the outside of the comb-box, so that when a bee comes back she can smell it. She will be sure to go into the box when she comes back, as the smell attracts the attention more than the flowers.

After a bee has been a few times, she will go straight off the box without whirling at all. Then if she is gone so long that you wish to "carry them" and set off again, you will now need your second catching-box. As the bees come back and alight on the comb you must catch them at once, by putting the catching-box over the comb-box. As they fly off to the glass, push in the slide, and you have them. Then take the other catching-box and do the same, and then put the two catching-box slides together, open both slides, and the bees will go into the top one; take the empty one to catch some more off the comb. When you have enough bees, you "go on the line" nearly as far as

you think the time they are gone will take them, allowing 15 minutes for a mile the first time a bee goes, then set off again, and so on until you find them. SUBSCRIBER.

Merrimack Co., N. H.

Noticing the request for information in bee-hunting, I will give my way.

Take honey fresh from the hive, and bees will work it during the months of June, July and August, as well as any other months of the year. Catch in your box from six to one dozen bees, then turn them loose on the honey, and while they are filling catch another box full, and by the time these have filled and returned, one will have a lively time watching them. I have been out twenty times during this month, and the bees have never worked better, altho we have flowers in abundance.

I found my first wild swarm in 1838, and have found over 1,000 bee-trees since. I have started a number of apiaries from wild bees. The bees I now have are all run-aways, that is, were taken from the woods, excepting the increase. I let them swarm naturally, yet none run away, nor do I lose any during the winter months.

PREVENTING WINTER LOSS—AFTER-SWARMS.

To prevent winter loss, have the hives arranged so you can examine them at any time. I look mine thru every week during the winter. I opened them the coldest day we had last winter, with the mercury from 25 to 35 degrees below zero, and found them lively and all right.

I close the hive nearly tight at the bottom (contrary to the advice of all experts), and have attached storm-doors or entrances, then arrange the entrances of the hives so there will be, like a refrigerator, free circulation within itself without outside influence. There will be dry air inside, never will be any dampness among the bees. The dampness and frost, if any, will all be above the cushion and above the bees. This arrangement is for wintering on the summer stands. We had any amount of honey down in this vicinity last season, yet there was no loss in wintering where they were properly fixed on the summer stands.

To make the second or after-swarms nearly equal to the first swarms, have ready a fertile queen, destroy the young queen, and introduce a fertile one ready to deposit eggs. In this way you will gain from two to three weeks. Calhoun Co., Mich. D. H. METCALF.

The Dickel Theory vs. the Dzierzon Non-Sperm Theory.

BY C. THEILMANN.

AT a bee-convention held in September, 1898, at Salzburg, Austria, Prof. Dickel brought out indisputable facts against the fallacy of the non-sperm theory. He gave the bee-keepers a very simple formula by which they could convince themselves of the correctness of his experiments. For nearly 50 years the Dzierzon theory, based on his observation, and supported by Prof. Siebold's microscopical experiments, was, that the queen has the faculty of laying impregnated and unimpregnated eggs at will. From the first-named, queens and workers develop, and from the latter, drones; and whoever said or wrote anything to the contrary were laughed at, or past unnoticed. Nevertheless, I have been convinced of the fallacy ever since July, 1883, when accidentally a colony of my bees gave me a glimpse into their secret laboratory, which is described on page 594 of the American Bee Journal for 1883. Probably not many of the present readers are in possession of it, therefore I will herewith give, in substance, the occurrence:

About the middle of July, 1883, I hived a swarm of full-blooded Cyprian bees on frames with starters; it was a big swarm. The queen was one year old, and one of the most prolific and regular layers I had in my apiary. I hived them about 10 a.m., and they went to work immediately in their new home. The next morning, on examination, I found the colony rather smaller than I wished to have them for comb honey production, as many bees went back to the parent hive.

Pretty soon a second swarm came out, which I decided to unite with the Cyprians. Knowing from previous sad experience of their sensitive and fighting character, I prepared some peppermint and sprayed them and the second swarm, which I had been shaking before the entrance, while in the meantime I shook the Cyprians from the frames on top of the swarm, and let them run into the hive

together; but the fighting began before they were all in, so I repeated the spraying and shaking of the frames, but the killing was still kept going. By this time other swarms came out to be attended to; I gave them another good pepperminting and closed the hive. I was kept busy at swarming and other things until dark.

The next morning I looked at my Cyprians, and found not a live bee in the hive. On examination I found on two frames new pieces of all-worker comb built about as big as my hand, one of which was filled with an egg in every cell regularly, as far as the cells were deep enough. Some of them had eggs when the cell was hardly $\frac{1}{8}$ -inch deep. There was not a drone-cell in the two pieces of comb.

After this close examination another swarm came out, which I put into this hive, and they went to work vigorously. About a week after I examined them, and found the frames filled with all drone-combs, except the two pieces above described. The one which had the eggs now had all capt brood, and scattered among it were about 25 drone pupae in enlarged worker-cells, and three queen-cells, and about 300 worker pupae. There was not an empty cell in the whole batch, as far as it contained eggs on both sides. There was no other brood or eggs in the hive. This last swarm undoubtedly lost its queen while swarming, and to save their existence they had produced queens, drones and workers from all worker-eggs, and no one can convince me otherwise since I made this experiment. It is evidence that the workers or nurse-bees can, at their selection, produce either sex at will by different food.

I am pleased that Prof. Dickel has found a way to get at the true facts without having to depend upon uncertain, fickle, unreliable analysis.

The formula of Prof. Dickel is this: Take the eggs from a drone-comb laid by a normal queen, and introduce them into worker-comb in a colony that has been queenless long enough to have become somewhat apathetic. The bees will not accept transferred eggs, but tear them out. The development of these eggs will show that workers and queens may be produced from drone-eggs.

Another: Remove from a drone-comb all larvæ and replace with just-hatched larvæ from a worker-comb, and give the one thus prepared to a colony under the same condition as before. You will then see queens and drones reared from the impregnated or worker-eggs even after they had hatched out.

Now I hope that many of our advanced bee-keepers and queen-breeders will try the experiments and report results.

In addition to the foregoing I recommend the formula I have under my treatment at present, which needs no artificial manipulation, and which almost any bee-keeper can try. It is as follows:

Give a swarm with a good laying queen on starters of foundation, in a good honey-flow. Let them build comb three or four days, then take out a frame of all worker-cells, stocked with 300 to 500 eggs, and give it to another just issued with a clipped queen. Cage the queen and lay her at the entrance of the new hive with the frame of eggs, and the rest filled with empty frames placed where the old hive stood, and where the swarm came from. The bees will come back to their queen and cluster about her. Let her be caged until sundown, then take her away and drive the bees into the hive; they will find the eggs before the next morning, and will stay and make use of the eggs as their instinct directs them, to save their existence, and in due time you will find queen, drone and worker pupae in the comb that was all worker-cells stocked with eggs of a fertile queen when given to the queenless swarm. Try this and convince yourselves of the long-disputed non-sperm theory in drone-eggs. Wabasha Co., Minn.

A Lecture on Controlling Sex in Bees.

BY PETER BOIS.

BEES-KEEPERS are able, in a measure, to regulate the production of drones in the hive, and cause the queen to produce almost entirely worker (female) bees, with but a small percentage of drone or male bees. This is effected to some extent by having almost all worker-comb in the hive and only a small amount of drone-comb. And I consider that bee-keepers have paid more attention to this matter of the production of sex, and that they have obtained better results than the breeders of other stock generally. I have been able to keep my colonies for several years past from swarming, and producing but very few drones per hive, while in worker-bees or female nurses my colonies

have been exceedingly strong. This has been achieved by noticing that drones were produced, and swarming also, when the queen in full "lay" received severe checks; these "checks," at such a time, I distinctly noticed, produced drones or male bees, while freedom from checks, which enabled a queen to go thru her laying season, produced female or workers only, with but very few males. If, therefore, beekeepers can govern the production of males at will, the breeders of other stock ought to be able to do the same if they know the law that affects the produce of male and female.

Fowl fanciers can induce birds to lay very early in the season, and ensure that a fair percentage of the eggs are fertile; but such eggs mostly produce cockerels, and the more fertile the hen the greater the percentage of cockerels. Now if we notice that checks are much more likely to be produced early in the season, when the weather is more variable than later on, and that these changes of temperature would chiefly affect the fowls whose ovaries were the most developed, we get at the reason why eggs set early produce a preponderance of male birds.

The queen-wasp gets in full "lay" more towards the fruiting part of the year than does the queen-bee, and at such time cold nights begin to set in, and greater atmospheric changes take place than during midsummer. This has the effect of causing her to produce some drone-eggs while she laid only worker-eggs previously. Animals generally are more equal in the production of males and females than bees and wasps. On the other hand, the queens of bees and wasps, altho their ovaries are far more largely developed than those of other animals, and would be thereby more liable to be affected by checks, yet they are better protected against outside influences than animals generally.

The mother-bee, like the mother-wasp, is in the midst of a full colony of her own progeny, which becomes an increase protection in proportion as the maternal ovaries become developed; secondly, they are fed with a food that can be made to produce but little variation in its influence; thirdly, they have the protection of the combs to guard them against sudden changes of temperature, and the combs of each of these insects, altho so widely different in the material of which each is composed, yet both are recognized as among the best non-conductors of heat and cold; fourthly, the hive in which they breed is so protected from extremes of temperature as to retain the warmth of the brood-nest in a very great degree while the queen-bee is extensively employed in egg-laying.

Other animals, while less fertile, are at all times far more exposed to outside influences, and this may in some measure account for their producing a more equal number of males and females than the two insects cited. I infer, therefore, from these observations, and others of a like nature, but all giving indirect evidence, that checks can, and do, affect the production of sex in the egg prior to fertilization, or at the time when the egg is ready for that purpose. More direct evidence, however, could, I think, be obtained by experimenting with the eggs of animals, such as frogs and fish, whose eggs are fertilized only after being laid.

The law which appears to govern the formation of sex—so far as checks are concerned—may be stated as follows: An egg which is fertilized free from check produces a female. In other words, a female is formed from an egg that has received no check in its fertilization when (or just prior to) being fertilized.

The following rules may also be stated with reference to the working of the law just cited: (1.) A female (mother) may be predisposed by anterior checks to produce males. (2.) A recent check exerts its greatest force, if received when the ovaries are nearing (or have just reached) their greatest development for egg-production. And, also, the more the ovaries have been favored towards extensive development, by prevailing favorable conditions, the greater is the effect in the direction I have indicated.

The eggs laid by a virgin queen clearly show the effect of an absolute check in producing males. When these eggs were ready for being fertilized, none of the elements necessary for the purpose were present; and they therefore received an absolute check, so far as fertilization, but possessing of themselves the necessary vitality to produce bee-life, but males only.

The eggs of a fertile queen-bee are free from check, and in consequence produce females. On the other hand, when she lays eggs that have received an absolute or extreme check, they are non-fertilized, and produce males that resemble the mother only. She also lays eggs that have

received a check sufficiently powerful to prevent them forming females, but that admits of their being fertilized with male semen; then they produce males in more or less degree resembling both parents. This latter case, which had not hitherto been solved, presents new interest, not only for the explanation it affords of the effects produced by the check described in the present instance, but because the effects of this check are also common to the eggs of animals generally. The effects produced by this check are therefore important to breeders of farm stock, or of domestic or pet animals, and also to fish-breeders as well as to bee-keepers; in fact, in every case where it may be desirable to specially produce females or males of any variety.

To control the formation of the sex in the egg at will is a science of itself, and some of the details to be attended to must be special to, and necessarily vary with, the kind of stock dealt with.—British Bee Journal.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

When Clover Yields Nectar.

On page 396, you say that white clover bloomed May 26. June 6 you were despondent on account of the failure of clover to secrete nectar. Is it not an accepted fact that clover does not yield nectar until it has been in bloom 10 days?

TENNESSEE.

ANSWER.—I don't know that I ever saw it stated as a generally accepted fact that clover does not yield nectar until it has been in bloom 10 days, but it has been a fact according to my own observation. What troubled me was that the bees did *not* begin to store nectar within 10 days after the first bloom appeared. Neither did it begin for some time after that, when the bees began to be excited over the harvest. But that soon died out, and the entire month of June past away with empty supers, some colonies during that time being at the point of starvation.

A Bunch of Six Questions.

1. I ordered a queen and introduced her; she did not lay more than a dozen eggs, and swarmed out after being in the hive 10 days. The bees settled and remained 15 minutes, and returned to the hive, but the queen did not return. It was a 4-frame nucleus, and well filled with bees. What was wrong with the queen? She was ordered for a tested queen; the breeder sent another one in her place.

2. I had two queens sent me the other day, arriving the next day after being mailed. In one cage the queen and all the bees were dead but three, and in the other the bees were all dead, and the queen could just crawl; she died in a few hours. They were not daubed up with candy, but seemed to be clean and dry. What was the trouble?

3. I live on an elevated place. I have my bees in a row facing the south, hives 20 inches apart, and a shelter over them 6 feet in front and and 4½ feet behind, and of course that runs the water off. At the back end, or north side of this shelter it is banked up to the roof to protect them from the north wind, as it would have a far sweep at them otherwise. Last winter it was very cold, and out of 43 colonies I lost 20, some being my strongest colonies, that froze or starved, as you may call it, but there was plenty of honey in the hives. There was frost in the inside walls of those hives. Nine colonies froze and 11 died of dysentery. Would you advise me to put my bee-hives in pairs, and pack them from now on? If so, when shall I pair them, and pack them, and how shall I pack them? It is not often we have such winters as last.

4. If I do not pack my bees would it not be better for

me to pair them? I lose a good many queens by trying to enter the wrong hive.

5. Would it be best for me to leave entrance open the full width of hive during winter, or close some of it up? I use an 8-frame hive 12 inches wide.

6. When there is a heavy snow on the ground, and the sun shines out, my bees fly out and the cold wind strikes them down. They fall in the snow and chill. Would you shut them in the hives to prevent their coming out at such times?

ALABAMA.

ANSWERS. 1. I don't know. It isn't certain that anything was wrong with the queen. Indeed, a queen that had life enough to swarm out would be considered all that you ought to expect of a dealer, and he did more than his full duty in replacing her.

2. Hard to tell without knowing more about it. Perhaps the candy was too dry, and hard.

3. The probability is that in your lifetime you'll never again see such another winter in the state of Alabama, and that your bees will winter just as well as in the past. Yet it might be no harm to pack hay, straw or other material in the shed.

4. It is a good plan to have the hives in pairs, making less danger of losing young queens. Move the hives together every few days, a few inches at a time.

5. Leave it open full width.

6. Put up boards to shade the hives, so the sun cannot shine in. But don't shut the entrance.

Unsealed Brood.

I have three swarms which were hived in June, each having a good queen and abundance of honey, but about one-half of the brood that ought to be sealed is unsealed. I do not know if it ever was sealed and was opened, or if it never was sealed. Nevertheless, this brood which ought to be sealed is in the state of a fully-developed bee, or nearly so; the head and feelers are from a white to a pink hue, and eyes are light brown in color. The other brood that is sealed looks healthy, and so does the unsealed larva of all ages. Brood-rearing seems to go on as if all was in the most healthy condition.

WEST VIRGINIA.

ANSWER.—You probably have a case of what is sometimes called bareheaded bees. The brood matures and the bees hatch out all right, but there is no capping. It is not certain what is the cause of the trouble, but I have a suspicion that it is caused by the wax-worm. What makes me think so is that it often happens that a row of these bareheaded bees appear in a line very much in the same shape as the gallery of a wax-worm. It only appears in small patches, or streaks, and if you have a case in which all the brood on the whole side of a comb remains unsealed, you have something I never saw nor heard of.

Queens from the South *Apis Dorsata*, Etc.

1. Do you think that queens from Texas stand the winter here as well as queens bred farther north? I have lost all the queens I have introduced from there. They die thru the winter in chaff hives.

2. Do you know who has any *Apis dorsata* queens for sale?

3. From which can the bees gather the most honey in a day, basswood or clover, each having the same chance?

4. Do the bees kill off the drones after swarming is over?

NEW YORK.

ANSWERS. 1. The general testimony seems to be that there is no difference in the hardiness of queens reared North and South.

2. The only *Apis dorsata* bees that have yet been offered for sale in this country are offered at 10 cents each by the A. I. Root Co., but they are not queens but workers, and they are preserved in alcohol. You may be pretty sure that when *Apis dorsata* queens are offered for sale alive in this country you will see prompt and prominent mention of it in this and other bee-papers. But don't set your hopes too high on stocking up with that kind of bees. If you had a queen of that kind, I don't believe you could get her to work in a colony of Italians or blacks. If you had a full colony of *Apis dorsata* bees, it is not at all likely you could get them to stay in a hive. No case has yet been reported in which any one has been successful in getting them to stay in a hive. Their nature is to have a single comb hung to

the limb of a tree, and the probability is that bees that naturally build a single very large comb in the open air will never submit to be shut up in a hive with several little combs. If you had a colony hanging to a tree as in their native land, it is not at all likely that you could by any possibility get them thru the winter in New York State.

3. According to reports given, the probability is that basswood would lead a considerable distance. Possibly two to one.

4. Sometimes, and sometimes not. There is no very sure rule as to the time drones are allowed to live, except that when a scarcity of pasturage occurs they must get out of the way, but all colonies are not alike as to that. Yet a colony with a good laying queen is not likely to support a lot of drones when no honey is coming in.

Joining Associations and Attending Conventions.

1. Which bee-keepers' association would it be best for me to join?

2. Do the lady bee-keepers attend the bee-conventions? I would like to go to the one at Philadelphia, if I can go.

3. I see the Central Texas Bee-Keepers' Association extends a cordial invitation to all bee-keepers, and says there will be no hotel bills to pay. Will it be that way at Philadelphia?

NEW JERSEY.

ANSWERS. 1. The United States Bee-Keepers' Association.

2. Ladies attend and are heartily welcomed. If possible, you ought by all means to attend.

3. No; the members attending the convention at Philadelphia will each one pay his own bills, but reasonable rates are always secured.

Pollen in Queen-Cells I had been taught to believe a sure sign of hopeless queenlessness. I think I've seen a number of exceptions. June 26 I met a plain case. In one of my "barns" I found on one comb three enlarged cells containing pollen, with the queen laying, and all going on prosperously.—Gleanings in Bee-Culture.

"The Queen of the Honey-Plants! Do you know it? If such is the case, you know of sweet clover or melilot. If you know of one better we shall be glad to hear of it." So says the editor of Bee-Chat. He says sweet clover is the only thing that will grow on salt marsh and reclaim it, so on the 4½ acres of sweet clover he has sown he has applied a ton of salt, a ton of ground bones, and 150 loads of farm-yard manure. He sows 14 pounds of seed to the acre.

House-Apiaries, after some experience, are highly esteemed by A. H. Duff, as he relates in the Bulletin of Kansas University. "Any old house" will answer him for a house-Apiary, but when specially constructed for the purpose he favors a small building 10 feet long, 6 feet wide, and 6 feet high, containing 11 colonies, 5 on each side and one at the end. He thinks this better than longer buildings, for in such the colonies near the ends get more than their proper share of bees at the expense of the central ones. In these small buildings ordinary hives are used, standing two inches from the wall.

To Paint or Not to Paint Hives? is a question discussed in the Progressive Bee-Keeper by Messrs. Doolittle and Aikin. Mr. Doolittle has said that he would not allow any one to paint his hives if the painter would give a dollar each for the privilege of painting them. Mr. Aikin replies that in the dry climate of Colorado unpainted hives, or any other thing made of wood, can scarcely be held together unless well painted. Put the best of lumber in a hive-cover, and let it be exposed to the sun for a year, and it will not hold water. Needless to say keep the hive in shade, for trees are too scarce in that country. But he says that bees may winter better in unpainted hives, for the lumber warps

and splits in the scorching sun and dry air, and the bees have so much ventilation that they winter well, and the air is so dry that 20 to 40 degrees more of cold can be endured than in a moister climate. His plan, however, would be to paint well to preserve the hive, then provide proper ventilation. Doolittle, while admitting that in Colorado he might paint, still thinks it would be better and cheaper to leave hives unpainted, then protect by means of a shadeboard covered with a sheet of 20x28 tin, allowing the air to pass freely between the cover of the hive and the shadeboard.

Acid for Cleansing Beeswax. It is generally known that acid is used in cleansing wax from old combs, but details of the matter have not been very freely given. The following specific information is given in Gleanings in Bee-Culture:

"The acid we use for refining beeswax is sulphuric—the ordinary commercial article. It should be reduced in water from 50 to 500 times. If the wax is then boiled in this water, or heated by a steam-pipe, and then allowed to stand for a few hours, it will turn to a bright lemon yellow. The amount of acid to be used will have to be determined by experiment. If you reduce it to one in a hundred, and then keep reducing as long as you can get the clarifying effect, you will get the proper solution."

Large Hives in Canada.—J. Cannek, in Gleanings in Bee-Culture, advises that in trying large hives they shall not be occupied by colonies with queens that have been bred in little hives for generations. He is disgusted with the statement of queen-breeders that good queens should fill eight Langstroth frames with brood before the honey-flow, and says:

"Why, Mr. Editor, at this date, May 9, I can show you lots of colonies in 'barns' with 9 and 10 frames filled with brood from one end to the other (frames considerably larger than the Dadant-Quimby,) and the hive boiling over with bees, and we have had a very backward spring—first pollen noticed April 18, and fruit-bloom just beginning to open. As you are aware, our honey-flow does not start for nearly a month, so you can see what, in my opinion, constitutes a good queen."

Large Hives.—As bearing upon the large-small-hive question, J. N. Harris gives an interesting contribution in Gleanings in Bee-Culture. It seems that hives too large are not desirable, 12-frame hives in his case being the happy medium. His figures make an interesting study. He says:

"I put into winter quarters 241 colonies in three apiaries, all in single-wall hives. They were wintered on the summer stands with no other protection than chaff in upper stories, and tight-board fences about the yards. They were in four sizes of hives on Langstroth frames:

| | | | |
|----------------|----------------|--------------|----|
| 37 colonies in | 8-frame hives, | winter loss, | 8 |
| 16 " | in 10-frame " | " " | 0 |
| 156 " | in 12-frame " | " " | 9 |
| 32 " | in 16-frame " | " " | 13 |

AVERAGE AMOUNT OF BROOD PER COLONY, APRIL 25.

| | | |
|---------------|-----------------|------------------|
| 8-frame hives | 3 | frames of brood. |
| 10-frame " | 3 $\frac{1}{4}$ | " " |
| 12-frame " | 5 | " " |
| 16-frame " | 2 $\frac{1}{2}$ | " " |

"It will be seen by the figures that I had the best success wintering in the 12-frame hive, which is my favorite size.

"The most of the 8-frame and all of the 10-frame hives were in the yard where the bees wintered best. I have always had fair success wintering in the 16-frame hive until last winter. The previous winter I had 103 colonies all in large hives, and lost but one colony."

Bees Breeding in Winter.—Dr. Mason said in the Bee-Keepers' Review that his bees bred in the cellar, and he believed they were stronger Jan. 21 than when put into the cellar in November, and not a sign of disease. Mr. Theilmann, in the American Bee-Keeper, thinks this is the first time any one has claimed that bees were stronger in January than in the preceding November, and hints that there may be some mistake about it. His own experience is that bees seldom breed in the cellar in December, and those which commence breeding in the latter part of January are pretty sure to have diarrhea before March 1. At one time he had a remarkably good opportunity to learn the amount of brood present in January, and relates the following:

"About Jan. 25, 1885, my bee-house, in which were 87 colonies, was burned. Altho the hives were saved, the bees, with the exception of three colonies, were smothered with

the smoke. Upon examination of the combs I found 48 colonies had more or less sealed brood or eggs; five of them had brood in five frames; two had brood in four frames; 17 had larvæ and eggs; 24 had eggs only. The remainder had neither brood nor eggs. All the combs were nice and clean, and there was no sign of disease. The temperature had been about 40° most of the time before the house burned."

It must be remembered, however, that bees wintered out-doors begin breeding earlier than those in the cellar.

Color of Honey.—Prof. Hunter's pamphlet gives photographs of six samples of honey in test-tubes. Beginning with the lightest, they range in shade as follows: 1, alfalfa and melon bloom; 2, white clover; 3, alfalfa; 4, basswood; 5, sweet clover; 6, knotweed. I suppose there's no little variation in different localities as to the shades of honey. Certainly I have always considered alfalfa lighter than white clover, but here it is darker. And is basswood usually darker than white clover? [The color of extracted honey from the same source varies greatly in different localities, and varies in the same locality in different years. Alfalfa, as a rule, I think, is lighter in color than white clover; basswood is generally a little darker, but only slightly so. Sweet clover is a little darker, on account of having somewhat of a greenish tinge. Knotweed or smartweed ought to be classed as amber, altho I have seen some samples that were very light-colored.—Ed.] Gleanings in Bee-Culture.

The Best Hive for Extracting.—J. M. Hambaugh was for years a neighbor of the Dadants, and adopted their style of hive with its large frame, so favorable in his opinion for successful wintering. Having settled in California, a change of conditions has allowed a change of preference, and he says in Gleanings in Bee-Culture:

"In starting anew here in California, with no wintering problem to solve, in the adoption of a frame that meets the requirements both of the bees and of the apiarist, I have adopted the regular standard Langstroth, and a hive to accommodate 10, and my reasons are:

"1. Its convenience in handling, and being nearest universal.

"2. Its size is as large as we dare to combine the feature of surplus and brood.

"3. Its best adaptation to combs when transferring.

"4. A case of 10 combs filled with honey is sufficient for the average man to lift, which is quite an item during the extracting season."

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 50 cents; 50 for 70 cents; 100 for \$1.25; 250 for \$2.75; 500 for \$4.50. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.

EXECUTIVE COMMITTEE—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE,
15, South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa.,
September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39. AUGUST 10, 1899. NO. 32.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Removing Comb Honey from the hives is quite a job for some bee-keepers, a few even not liking the bee-escape method. We have mentioned it before in these columns, we believe, that Dr. Miller uses a large wire-cloth pyramid sewed over a hole in a piece of heavy cloth larger than to cover a super, so that the edges can hang over. He then piles up eight or ten supers full of honey, and puts the escape on top of the pile, leaving it there until the bees have gone up and out thru the escape.

We found a good plan is to lay a regular bee-escape board crosswise on top of an empty super or box on the ground, which leaves an open space at each side of the escape-board. Then pile on the supers of honey from several hives, and on top of all invert another bee-escape board. We have done this towards evening, and by the next afternoon all the bees were gone back to their hives, and the honey was removed just as you would take bricks out of a wagon-box. By using two escape-boards the bees can go both ways out below and out at the top of the pile of supers. It works splendidly, and by this method only a few escape-boards are needed in an apiary of quite a good size.

The Philadelphia Convention will be in session in less than one month. The time is short. We would be glad to announce the names of those who expect to be present, especially the ones who come from a distance. It is nice to

know in advance who expects to be there, and it might also induce some hesitating ones to decide to attend. It is worth much to meet the leading bee-keepers of the country.

We felt well repaid for attending the Buffalo convention two years ago, where we met so many splendid bee-keepers, among whom we might mention P. H. Elwood, Capt. Hetherington, and G. M. Doolittle, of New York; R. F. Holtermann, F. A. Gemmill and D. W. Heise, of Canada; J. F. McIntyre, of California; F. Danzenbaker, and many, many others that it was a delight to meet and talk with. It is always an inspiration to meet in annual convention so many who have contributed so much toward the progress and success of bee-keeping in this country. We trust that just as many of our readers as possibly can do so will arrange to be present at the Philadelphia meeting, Sept. 5, 6 and 7.

LATER.—Since writing the foregoing, we have received a letter from Secretary Mason, in which he says:

"Mr. Hahman, of Philadelphia, writes that they expect a large gathering, and applications are being made for entertainment as per request in the American Bee Journal, and I presume many more will send in when they get the notice in the August bee-papers."

If you have not already done so, and you are going to attend the convention, write *at once* to Mr. Hahman, Harrowgate Lane, Sta. F., Philadelphia, Pa., and he will engage a room for you. Mr. Hahman is secretary of the Philadelphia Bee-Keepers' Association.

Honey in Hotels.—One cannot help wishing that honey might be more commonly found on hotel tables in this country, upon reading in Ostdeutsche Bienenzuchterei that the use of honey has become a need to the traveling public, so that the hotels in many regions, especially hotels of the better class, find themselves obliged to serve honey as well as butter, making no little demand thereby.

The Leisure of Bee-Keepers is a thing that F. L. Thompson, writing for the Progressive Bee-Keeper, thinks should be carefully guarded. The business is such that at certain times in the year there is little or nothing a bee-keeper can do, and at such times he protests against the time being put in at peddling honey under the plea that because one man has made a success at peddling another can. His idea is that instead of so much talk about cultivating the home market, the honey-trade should go thru the usual channels, for people go to the groceries for their food, and the groceries go to the wholesale houses for their stock. Short cuts should be also studied, so as to have more leisure, "that is, the opportunity for disinterested activity."

The Kingbird a Bee-Enemy.—A. J. Wright, the man who made the remarkable statement that some animals see by means of rays of dark instead of light, having been criticized for it, makes reply that after much observation he is "convinced that many animals can see perfectly *only* in total darkness." However wild his views may be on that point, he gives in Gleanings in Bee-Culture some very interesting observations with regard to the kingbird. A report of the Secretary of Agriculture made out the kingbird as innocent, because the stomachs of 171 kingbirds were collected in 19 States, Canada, and the District of Columbia, and only 14 stomachs contained any traces of the honey-bee, and a total of only 50 bees were found, and of these only 4 were workers.

Then Mr. Wright gives a very interesting account of his own investigations. At six in the morning, when no drones were flying, he shot a kingbird right among the bees after seeing him capture six of them. Cutting the

bird open, he found no trace of a bee in any part. Then at two, when drones were plenty, he tried it again. After seeing a kingbird capture ten or more bees, he shot it and found in the first stomach one drone and nothing else, and in the second stomach fragments of insects, but nothing could be classified. Mr. Wright says, "You may shoot kingbirds all day, and the chances are '16 to 1' that you won't find a worker, and rarely a drone, in the stomachs of the entire lot."

The seeming mystery of so many bees being caught, and so few found on dissection, is thus explained:

"This bird seizes a worker, which he much prefers to a drone, by the abdomen, giving the bee a few smart raps against the perch. He then passes the body of the bee its entire length transversely between his upper and lower mandibles, by a peculiar motion of the latter. This is continued until the juices are thoroly extracted, when he opens his mouth and drops the useless carcass to the ground. No wonder, then, that we failed to find workers in the stomach. But how about the drones? Well, when a drone is seized he is swallowed at once; and when several have been taken into the first stomach the bird sits quietly on the perch for half an hour, sometimes longer, when by a few motions of the neck, the casting is brought up. This is about the size and shape of an ordinary pea, and consists of the hard, indigestible portions of insects."

The Illinois State Fair will be held at Springfield this year, Sept. 25 to 30. The list of cash premiums offered on bees, honey, etc., are as follows, being "open to the world" for competition:

| | 1st. Prm. | 2nd. Prm. | 3rd. Prm. |
|---|-----------|-----------|-----------|
| Display of comb honey..... | \$20 | \$15 | \$5 |
| Collection of labeled cases containing 12 or more pounds of white honey from different flowers..... | 8 | 5 | 3 |
| Collection of labeled cases containing 12 or more pounds of amber or dark honey from different flowers..... | 8 | 5 | 3 |
| Case white clover comb honey, 12 to 24 pounds..... | 4 | 3 | 2 |
| Case basswood comb honey, 12 to 24 pounds..... | 4 | 3 | 2 |
| Case amber comb honey, 12 to 24 pounds..... | 4 | 3 | 2 |
| Display extracted honey..... | 20 | 15 | 10 |
| Display of honey extracted on the grounds..... | 5 | 3 | 2 |
| Frame of comb honey for extracting..... | 5 | 3 | 2 |
| Display of candied honey..... | 20 | 15 | 10 |
| Display of beeswax..... | 12 | 8 | 4 |
| One-frame observatory hive dark Italian bees..... | 4 | 3 | 2 |
| One-frame observatory hive golden Italian bees..... | 4 | 3 | 2 |
| One-frame observatory hive Carniolan bees..... | 4 | 3 | 2 |
| Honey-vinegar, 1/2 gallon, with recipe for making..... | 4 | 3 | 1 |

The judges in this lot will be governed by the code of rules adopted by the Illinois State Bee-Keepers' Association.

Five hundred pounds will receive full score for quantity in displays of comb and extracted honey. Fifty pounds will receive full score for quantity in display of beeswax.

There is a total sum of \$268 offered in the above list, which should call out a good display from the bee-keepers of Illinois. The State Fair authorities have for several years allotted a splendid space for the apiarian exhibit, and have been generous in their cash premium offers. Mr. H. J. Cater, the superintendent of the apiary department, has also done his best for the interests of bee-keepers ever since he has had charge of the work. The honey-producers of the State should encourage him to do even better by making this year the largest and finest exhibit ever shown.

"Stands" for "Colonies."—In one of the bee-papers for June we find a question asked in regard to "preventing increase in the number of stands." This would have been easily answered by advising the purchase or manufacture of a less number. A "stand" now means the wooden frame or foundation upon which the hive proper rests, tho the querist evidently used it to mean "colonies." It is a good thing sometimes for editors to help their correspondents to get things straight.

The Pennsylvania Lines is perhaps the greatest railroad system on this continent. It is also the direct route from Chicago to Philadelphia—where the United States Bee-Keepers' Association will hold its 30th annual convention next month, Sept. 5, 6 and 7. Less than a month yet, and then there should be assembled the largest convention of bee-keepers ever held on this continent.

On the Pennsylvania Lines the round-trip fare from Chicago will be only \$16.45, being one cent a mile each way, as it is just 822 miles from Chicago to Philadelphia. The reason of this low rate is the 33rd national encampment of the Grand Army of the Republic, which meets at Philadelphia Sept. 4 to 9. Tickets will be on sale Sept. 1, 2, 3 and 4, inclusive.

The editor of the American Bee Journal and Dr. C. C. Miller expect to go on the Pennsylvania Lines, leaving Chicago at 3 p.m., Monday, Sept. 4, arriving in Philadelphia the next day about 6 p.m. Now, why cannot a large company of bee-keepers from the West arrange to go on that same train? We will see to it that splendid accommodations are secured for all who will notify us in time that they will go over the Pennsylvania Lines from Chicago.

Next week we will have more to say in regard to the trip to Philadelphia. In the meantime, if further information is desired, write to Mr. H. R. Dering, the affable Assistant General Passenger Agent of the Pennsylvania Lines, addressing him at Chicago, Ill.

Talking Bees to School Children.—On page 360 we mentioned having given a bee-talk to the children in the eighth grade of the McPherson school, who were under the careful instruction of Mrs. Lane. Referring to this rather "new thing," Stenog in Gleanings in Bee-Culture offered this encouraging remark:

The following is clipped from the Chicagoan of May 27: "A rare treat was given to the eighth-grade pupils of the McPherson school last Thursday, when Mr. George W. York, editor of the American Bee Journal, gave them an illustrated lecture on bees. The pupils were delighted, and the way Mr. York described the simple animal was truly wonderful."

Mr. York says his reason for copying the item was to suggest that bee-keepers in other cities will find the school children greatly interested in a talk on bees if given a chance. He had a Langstroth frame of bees in a glass hive, and gave therefrom a practical illustration of the work of bees in the hive. That is a grand idea, and ought to be carried out wherever possible. Mr. York deserves the thanks of all for taking the initiative step. The children were to take notes and print them in their little school-paper. "A chiel's amang ye, takin' notes; an', faith, he'll prent it."

Well, the result of the "takin' notes" is the following, written by Miss Anna Sundberg—a pupil 15 years of age—who also drew the pictures that are shown, all of which appeared in the school's June paper, called "The McPherson":

BEEES.

Thursday afternoon Mr. York was in our room and told us a great many interesting things about bees.

There are three kinds of bees, the queen, the workers and the drones. The queen is long and narrow. She lays all the eggs in the hive, but never gathers honey nor goes where the surplus is stored. Her food consists of a finer quality of honey, called royal jelly.

The worker is like the queen in every way except two. The first is that the lower part of its body is shorter, and the second is, that its work is different. It gathers the honey and pollen, which it stores away in the cells.

The drone is larger and broader than the worker. It does nothing but eat and sleep.

The pollen is stored in the lower part of the hive, and

here the queen lays her eggs. One egg is put into each cell. After the egg has been laid and food put in for the larva, the workers plaster up the opening of the cell. There is some difference in the covering of the cells. Those of workers are flat, while the drone-cell caps resemble a mass of bullets, and the entire queen-cell is different. Her cell looks like a bag, and is shaped somewhat like a peanut. A few days after being laid each egg is transformed into a small, pearly-white larva.

The queen develops in 16 days, the worker in 21, and the drone in 24.

The workers seldom lay eggs, but when they do only drones are produced.

Bees will gather honey for several miles around. The bee flies around the hive several times before it leaves, and

when it comes back it flies to a certain height, and then in one straight line to its home.

☐ The drones have no stings. The worker dies after using its sting, and the queen only uses hers in killing a rival, if she has any.

There are about 40,000 bees in a hive, and a strong colony of bees will store about 100 pounds of honey in a good season.

When the hive is overcrowded, the queen and a great many of the workers fly away and settle on the branch of some tree. This is called swarming, and causes a great deal of excitement in the hive when it happens.

ANNA SUNDBERG.

When it is known that the foregoing was written entirely from memory, after hearing the bee-talk, it will be all the more surprising that "Anna" was able to get the "story" so nearly correct in every particular. We think she also did well in making the two illustrations.

We hope it may all help to encourage others to try the experiment of taking bees into the school-rooms, and telling the children about their (the bees') wonderful habits and work.

MR. WM. M. WHITNEY, of Kankakee Co., Ill., wrote us July 29:

"My bees are booming. I have already taken over 70 pounds from each of some colonies."

MR. E. S. LOVESY, of Salt Lake Co., Utah, wrote us July 31:

"In some favored localities the honey-flow appears to be all right, but the rule is otherwise this season, ranging from one-third to two-thirds of a crop."

FREIFRAU V. BERLEPSCH died March 29, 1899. She was the widow of Germany's greatest writer on bee-culture, Baron v. Berlepsch. She is said to have assisted the Baron very materially in his literary work. Since he died she has always taken active part in the bee-keepers' gatherings. Dzierzon and Freifrau v. Berlepsch have characterized the Wanderversammlung for many years. American Bee-Keeper.

RAMBLER (J. H. Martin), in Gleanings in Bee-Culture, gives a temperance lesson that is worth repeating. It seems in his ramblings he was compelled to stay over night at a hostelry that had a saloon attachment. There must have been a lively time, for he says:

"During the struggle between the men and the beer-bottles I made my escape to a barber-shop. Here I found a congenial artist, and we straightway fell into conversation upon the hard times and the scarcity of money.

"Say, stranger," said he, "I have just had my eyes opened about the cause of hard times during this Thanksgiving. We have three saloons here, and each one of them puts up turkeys for a raffle. The poor laboring men all rush in and raffled away their money, some individuals as much as \$5.00, and then getting no turkey; and (do you believe it?) the saloons in this little one-horse town cleared \$100 each. I used to do just such things; but a few years ago I found myself. Talk about hard times! just banish the saloon and you would see the best times on record."

"I fervently said, 'Amen!'"

There would be no hard times in many homes if the cursed and cursing saloon were banished. "The saloon must go" before most of the poverty and suffering of this world leaves.

MR. R. G. HAWN, of Kittitas Co., Wash., enquires as to the "formula for making candy out of honey—not bee-candy, but candy for the human candy-eaters." He evidently is not supplied with our Honey Almanac. Among its many recipes he will find this one—originated by Dr. C. C. Miller, who vouches for its producing something fine:

"HONEY CARAMELS.—One cup extracted honey of best flavor, 1 cup granulated sugar, 3 tablespoonfuls sweet cream or milk. Boil to "soft crack," or until it hardens when dropt into cold water, but not too brittle—just so it will form into a soft ball when taken in the fingers. Pour into a greast dish, stirring in a teaspoonful extract of vanilla just before taking off. Let it be $\frac{1}{2}$ or $\frac{3}{4}$ inch deep in the dish; and as it cools cut in squares, and wrap each square in paraffine paper, such as grocers wrap butter in.

"To make chocolate caramels, add to the foregoing one tablespoonful of melted chocolate, just before taking off the stove, stirring it in well. For chocolate caramels it is not so important that the honey be of best quality."

THE LEAHY MFG. Co., as all know, are among our regular yearly advertisers. We notice in the July Progressive Bee-Keeper they have this to say about their present season's business, which shows evident satisfaction on their part:

"Business at this date is still good, and we are having about all we can take care of in ten hours a day. The last season has been the best in our experience, and our output was a third larger than ever before. From Dec. 15 until the last days of June, we ran overtime continually, part of the time 22 hours a day, and part 15 hours a day. We surely got all the trade we wanted, and then some more, and we took pretty good care of it, too, even if it did come nearly killing us all. Don't believe we ever want so large a trade again to fill in so short a space of time."

EDITOR W. Z. HUTCHINSON, of the Bee-Keepers' Review, dropt in to see us for about half an hour when in Chicago on his way home from a two-weeks' trip among Wisconsin bee-keepers and bee-supply manufacturers. We regretted that his stay was necessarily so short. He reports that there will not be a very large crop of honey in Wisconsin this year.

IT WORKT TOO WELL.—"They say that electricity is a sure antidote for the sting of bees," said the electrical enthusiast.

"Yes, I've tried it," said the student.

"Really? How did it work?"

"Well, a bee stung me, and it hurt so that I applied the electricity. After that I went over and sat down in a hornet's nest to see if I couldn't get over the effects of the cure."

The Premiums offered on page 508 are well worth working for. Look at them.

Root's Column

GLEANINGS AT REDUCED RATES....

We do not need to tell you about our journal, for it will speak for itself; but as an extra inducement we make the following low offers:

Offer No. A.

For 25 cents we will send GLEANINGS IN BEE-CULTURE from the time your subscription is received until January, 1900. If you send in your order promptly you will get 6 months for only 25 cents.

Offer No. B.

For \$1.00 we will send an untested Italian Queen worth 75 cts. and GLEANINGS IN BEE-CULTURE one year.

Offer No. C.

For \$1.00 we will send GLEANINGS IN BEE-CULTURE the rest of this year and all of next year, that is, from the time your subscription is received until January, 1901. The sooner you take advantage of this offer, the more numbers you will receive.

Offer No. D.

For 50 cents we will send GLEANINGS IN BEE-CULTURE 6 months beginning July 1 and Vol. I of Gleanings. This is for the year 1873. There are many interesting things. There are 12 articles on "Starting an Apiary," and while some of these may not be practical now, there is much valuable information and it gives a good idea of bee-keeping at that time. Our supply is limited and of course we cannot continue this offer long.

Old as well as new subscribers may take advantage of these offers, but all arrearages on back subscriptions must first be paid at \$1.00 per year.

ADDRESS

THE A. I. ROOT CO.
MEDINA, OHIO.

Our Roll of Honor.

Some time ago Gleanings in Bee-Culture published what it was pleased to call its "Roll of Honor," being subscribers who had taken that paper ever since its beginning, or 25 years. We also made a call for those who had taken the American Bee Journal 25 or more years, and among those who responded are the following:

FRIEND YORK—We have read your call for readers of American Bee Journal for over 25 years, and we respond at once. We have taken the American Bee Journal from the beginning, and my father began contributing to its pages in November, 1867, or over 31 years ago. We have also advertised in its pages for about 30 years.
Hancock Co., Ill. C. P. DADANT.

FRIEND YORK—I have been a reader of the American Bee Journal for 30 years.
Lake Co., Ill. F. GRABBE.

EDITOR YORK—I have taken every number of the old "American Bee Journal" from its first editor up to its present one. How many years it would make in all this time I cannot tell.

The Bee Journal is my old, old friend, and as long as the bee-hive can be seen in my yard the old Bee Journal can be seen in my house.

Our family came to this territory of Wisconsin in 1840. Our home was near the shore of that beauty of all lakes in the northwest, "Green Lake." We were 30 miles from a white man for a number of years. The Winnebago Indians told us the first swarm of bees was seen flying over to the west only a year or two before we came; then they knew the white man was coming close by.

My first bees came from the bee-tree; then came in use the log hive; then the old box, and next the drawer in the back of the new box-hive. I have lived thru all of these changes with my old friend, the honey-bee, to the present time. R. DART.

Fond du Lac Co., Wis.

EDITOR YORK—In answer to your call for old subscribers to the Bee Journal, I will say that I have paid for and received all the numbers published since December, 1863, and had gotten quite a start on the road as a bee-keeper before I ever saw a bee-paper, as I had at that time over 100 colonies all in box-hives.

I began bee-keeping in 1852 with four colonies, and increased that number so that at the close of the season of 1857, I had 120 colonies, with two-thirds of them in a starving condition, on account of a hard frost on the morning of July 4 of that year. I did not know they could be fed, and all were lost that did not have enough honey to live on, but that was the last time that I let a colony starve, if I knew they needed help.

In 1859 I had gotten well started again, when foul brood made its appearance, and for two years it cost me quite a number of colonies, and had it not been for "Mysteries of Bee-Keeping Explained," by the noble and gifted Quinby, I have no doubt that I would have quit the business; but as it happened, Quinby's book fell into my hands just in time to save all not too badly off, as he gave the cure for it that has never been improved on; and in all these years since I have had but one case, and for over 20 years I have not seen a case, and no foul brood is known in all this locality where thousands of colonies are kept.

For 46 years I have spent my time with the honey-bee, but now the rheumatism claims all my time, and in the spring of

SWEET CLOVER

And Several Other Clover Seeds.

We have made arrangements so that we can furnish Seed of several of the Clovers by freight or express, at the following prices, cash with the order:

| | 5lb | 10lb | 25lb | 50lb |
|------------------------------|------|--------|--------|--------|
| Sweet Clover (melilot) | .60c | \$1.00 | \$2.25 | \$4.00 |
| Alsike Clover | .70c | 1.25 | 3.00 | 5.75 |
| White Clover | .80c | 1.40 | 3.00 | 5.00 |
| Alfalfa Clover | .90c | 1.20 | 2.75 | 5.00 |
| Crimson Clover | .55c | .90 | 2.00 | 3.50 |

Prices subject to market changes.

Add 25 cents to your order, for cartage, if wanted by freight.

Your orders are solicited.

LEININGER BROS.
Ft. Jennings, Ohio.
Please mention Bee Journal when writing.

1898 I sold them all to one man, and his first crop was about 8,000 pounds of nearly all comb honey.

I have always worked for comb honey, and my first honey-boxes held from 10 to 50 pounds—big boxes on big hives, and the small ones on the small hives, for then I made hives to match the size of the swarm to be hived. I learned early in my experience with bees that large, strong colonies were the ones that gave me the best returns for the care I gave them.

Dadant is only one of the thousands of bee-keepers that use large hives for the production of comb honey as well as extracted.

Now, Friend York, I will stop writing, for I have already said too much just to tell you how long I had taken the American Bee Journal. **IRA BARBER,**
St. Lawrence Co., N. Y.

EDITOR YORK:—I have been a regular subscriber to the "Old Reliable" since 1867, since which time I have received and read every number. In all, it makes over 30 years. I have been among bees since my earliest recollection, with the exception of two years, our folks having bees when I was young. When I was 14 years old, father gave me a swarm. The next year (1857) I had one swarm from the old one, and that fall we came away from York State, so I sold my two colonies of bees, which were in straw hives.

In March, 1860, I bought a colony in a box-hive, and have kept bees here since that time, or in all I have had bees 41 years. In 1867 I transferred all my bees into movable-comb hives, and have since used such

wholly. I have tried numerous styles of hives on a small scale, and later, after a good trial, discarded all but the one I now use and prefer. Up to a few years ago I read all the books on bee-culture published in this country, and took as high as five different bee-papers for a number of years. I was enthusiastic, and blunders were common. I bought my first Italian queens in June, 1867.

Success to the American Bee Journal. Long may its banner wave!
Carroll Co., Ill. F. A. SNELL.

I have taken the American Bee Journal 25 years, including this year.
Wayne Co., N. Y. D. M. KETCHAM.

The wish was expressed by the editor, that those of subscribers who had taken the American Bee Journal for 25 years or more should send in their names. In accordance with that I will make the following statement:

In the year 1870 or 1871, I secured a copy of a bee-paper published in Ohio, I think, by a man by the name of King, and in the course of that year I learned of the existence of the American Bee Journal, sent for and obtained a copy, and liked it so well that I subscribed for it, and have taken it every year but one since, I think.
Wyoming Co., N. Y. DAVID HALL.

BRO. YORK:—In answer to your request, in regard to the number of years I have taken the American Bee Journal, I would say that I got my first hive in 1872, and subscribed for the American Bee Journal soon after, so that it must be 25 or 26 years, to the best of my knowledge and belief.
Lancaster Co., Pa. THOS. THURLOW.

FRIEND YORK:—I see you call for a roll of honor, for all who have taken the American Bee Journal for 25 years. I have done better than that; I have taken it ever since it was published by A. M. Spangler & Co., 25 North 6th St., Philadelphia, Jan. 1, 1861, and I have nearly every number now. There are a few numbers I have lost in the mail, and I have neglected to get them. I have been in the bee-business ever since. I had the first extractor in this county, and shipped the first extracted honey from this county. I was the second one to introduce Italian bees. I have over 600 colo-

nies to look after now, and I produced a big carload of honey in 1898. I taught my brother, W. L. Coggs, how to keep bees, and was in partnership with him several years, under the name of Coggs Bros. I built the first movable-frame hives in this section, and have lived to see bee-keeping advance from almost nothing to what it is now. D. H. COGGS.

Tompkins Co., N. Y.

As you call for names of those who have been subscribers to the American Bee Journal for 25 years or more, I will say that I commenced in the bee-business in 1870, working for and learning from a bee-keeper. The following year I established myself with bees on shares. That year (1871), if I am not mistaken, I began taking the American Bee Journal, and have taken it ever since. I have all the numbers since the beginning of my subscription, but do not have time now to look up the exact date of commencement.

The Bee Journal has improved much since you took hold of it. I am not thru learning yet. W. M. MUTH-RASMUSSEN.

Inyo Co., Calif.

I have been a subscriber to the American Bee Journal, without intermission, since 1870, and have all the numbers from then to the present time. JAS. POINDEXTER.

McLean Co., Ill.

I have taken the American Bee Journal since January, 1873, or about 27 years.

Albany Co., N. Y.

W. S. WARD.

I have taken the American Bee Journal ever since January, 1873. I have all the volumes but one up to the present time.

Ontario, Canada.

W. C. WELLS.

I have taken the American Bee Journal about 30 years.

GEO. J. STRAY.

Branch Co., Mich.

I have been a regular reader of the American Bee Journal since 1871—over 25 years, and am not tired of it yet. I have been a bee-keeper over 60 years. I was born in 1828—71 years ago. I have learned a good deal about bees, but have not learned all yet. Some things I know, and a heap of things I don't know.

Hunt Co., Tex.

W. R. GRAHAM.

I have taken the American Bee Journal ever since it was published in 1871, by Samuel Wagner, and have about all the back volumes since 1861, purchased from Thomas G. Newman. I cannot do without the "Old Reliable," and think it improves as the years go by. It arrives here on Friday, and I have never mist receiving a number in the 27 years that I have taken it.

Fayette Co., Pa.

W. L. KEMP.

You are not perhaps aware that I am among the oldest subscribers to the American Bee Journal. I have been receiving it most regularly since July 1, 1868, and I can endorse the expression now often applied to it—"The Old Reliable." I have been reading it with great profit, as it past from one editor to another, from Samuel Wagner to the present day. We have it now, instead of its visits to our homes every month, coming every week, and instead of paying two dollars for it, as we did at its commencement, only pay the small sum of one dollar for it annually, tho it contains stores of excellent and interesting reading connected with everything belonging to bee-keeping. I hope its course will continue to advance in the future as in the past. I for one feel satisfied with the Journal; and wish its pushing and enthusiastic editor all success.

REV. JOHN ANDERSON.

Tiverton, Ont.

FRIEND YORK:—I notice what you say about subscribers who have taken the American Bee Journal for 25 years or more. I don't know whether I belong in the class or not, but if I don't I am not far behind.

I commenced taking it at the beginning of 1870—just 29 years ago—when Samuel Wagner was editor. I took it steadily until just before you took hold of it, when for reasons you care nothing about, I dropt it, beginning again a few years ago. Now, I don't know what years it was I was out of the family, nor just how many years, but I think from 3 to 5. You see, no one knows for certain whether I am on your roll of 25-year veterans or not.

With the exception of Mr. Wagner, and the one who had charge for a short time after his death, I have enjoyed the personal acquaintance of all its editors, and have past a number of pleasant hours in its sanctums. It is not probable that I will ever again visit it in its own home, but it will probably be a regular visitor in mine as long as I live and am able to read it.

What an immense advance has been accomplished in the methods and results in bee-keeping since the American Bee Journal first came into my home! and how much I owe it for my own success in the business is hard to estimate. Hoping the end of the next 25 years will find you still at the helm, and its present high character sustained, I am, Very truly yours,
Dade Co., Fla. O. O. POPPLETON.

"The Page" Can Withstand Any Stock Rampages.

"FARM FENCES.—The worm, staked-and-ridered, or post-and-rail fences that satisfied our fathers are fast giving way to wire fences in all sections of the country, and it has now come to a point where wire is the only material considered by the progressive, up-to-date farmer when it comes to the fence question.

"Every farmer should remember that the Page Fence, made by the Page Woven Wire Fence Co., of Adrian, Mich., must not be confounded with the inferior grades of wire fencing that some adventurers are trying to foist upon farmers. It is high up among the standard fences of the world, and is as cheap as any other good woven wire fence. Remember, it is made entirely from hard spring-steel wire, coiled without twisting, and galvanized, and that two men can, without previous experience, easily erect a mile in one day after the posts are set. There could not be a better fence."—Farm and Fireside.

Send your name and address to the Page Woven Wire Fence Co., Adrian, Mich., and get the "Page Fence Age" free for six months. Be sure to say you saw their advertisement in the old American Bee Journal.

BEE-BOOKS

SENT POSTPAID BY

George W. York & Co. 118 Mich. St. Chicago.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—It is nicely illustrated, contains 160 pages, beautifully printed in the highest style of the art, and bound in cloth, gold-lettered. Price, in cloth, 75 cents; in paper, 50 cents.

Langstroth on the Honey-Bee, revised by Dadant.—This classic in bee-culture has been entirely re-written, and is fully illustrated. It treats of everything relating to bees and bee-keeping. No apiarian library is complete without this standard work by Rev. L. L. Langstroth—the Father of American Bee-Culture. It has 520 pages, bound in cloth. Price, \$1.25.

Bee-Keepers' Guide, or Manual of the Apiary, by Prof. A. J. Cook, of the Michigan Agricultural College.—This book is not only instructive and helpful as a guide in bee-keeping, but is interesting and thoroughly practical and scientific. It contains a full delineation of the anatomy and physiology of bees. 460 pages, bound in cloth and fully illustrated. Price, \$1.25.

Scientific Queen-Rearing, as Practically Applied, by G. M. Doolittle.—A method by which the very best of queen-bees are reared in perfect accord with Nature's way. Bound in cloth and illustrated. Price, \$1.00.

A B C of Bee-Culture, by A. I. Root.—A cyclopaedia of 400 pages, describing everything pertaining to the care of the honey-bees. Contains 300 engravings. It was written especially for beginners. Bound in cloth. Price, \$1.20.

Advanced Bee-Culture, Its Methods and Management, by W. Z. Hutchinson.—The author of this work is a practical and entertaining writer. You should read his book; 90 pages, bound in paper, and illustrated. Price, 50 cents.

Rational Bee-Keeping, by Dr. John Dzierzon.—This is a translation of his latest German book on bee-culture. It has 350 pages, bound in paper covers, \$1.00.

Bienen-Kultur, by Thos. G. Newman.—This is a German translation of the principal portion of the book called "Bees and Honey." 100-page pamphlet. Price, 25 cents.

Bieneznucht und Honiggewinnung, nach der neuesten methode (German) by J. F. Eggers.—This book gives the latest and most approved methods of bee-keeping in an easy, comprehensive style, with illustrations to suit the subject. 50 pages, board cover. Price, 50 cents.

Bee-Keeping for Beginners, by Dr. J. P. H. Brown, of Georgia.—A practical and concise treatise on the honey-bee, giving the best modes of management in order to secure the most profit. 110 pages, bound in paper. Price, 50 cts.

Bee-Keeping for Profit, by Dr. G. L. Tinker.—Revised and enlarged. It details the author's "new system, or how to get the largest yields of comb or extracted honey." 80 pages, illustrated. Price, 25 cents.

Apiary Register, by Thomas G. Newman.—Devotes two pages to a colony. Leather binding. Price, for 50 colonies, \$1.00; for 100 colonies, \$1.25.

Dr. Howard's Book on Foul Brood.—Gives the McEvoy Treatment and reviews the experiments of others. Price, 25 cents.

Winter Problem in Bee-Keeping, by G. R. Pierce.—Result of 25 years' experience. 30 cts.

Foul Brood Treatment, by Prof. F. R. Cheshire.—Its Cause and Prevention. Price, 10 cts.

Foul Brood, by A. R. Kohuke.—Origin, Development and Cure. Price, 10 cents.

Capons and Caponizing, by Dr. Sawyer, Fanny Field, and others. Illustrated. All about caponizing fowls, and thus how to make the most money in poultry-raising. 64 pages. Price, 20c.

Our Poultry Doctor, or Health in the Poultry Yard and How to Cure Sick Fowls, by Fanny Field. Everything about Poultry Diseases and their Cure. 64 pages. Price, 20 cents.

Poultry for Market and Poultry for Profit, by Fanny Field.—Tells everything about Poultry Business. 64 pages. Price, 20 cents.

York's Honey Almanac is a neat little 24-page pamphlet especially gotten up with a view to creating a demand for honey. A very effective helper in working up a home market for honey. Prices: A sample for a stamp; 25 copies for 40c; 50 for 60c; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Page & Lyon Mfg. Co.

NEW LONDON, WIS.,

Operates two Sawmills that cut, annually, eight million feet of lumber, thus securing the best lumber at the lowest price for the manufacture of **Bee-Keepers' Supplies...**

They have also one of the **LARGEST FACTORIES** and the latest and most improved machinery for the manufacture of **Bee-Hives, Sections, &c.**, that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the **clearest and whitest Basswood** is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the **BEST GOODS AT THE LOWEST PRICES.**

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, July 19.—A little comb honey is coming and the best white in pound sections brings 15 cents; some of it is not properly sealed and leaks from those few uncap cells sufficiently to stain the cases and thus detract from its value. Amber grades, 10 1/2 to 11 cents, and dark, 7 1/2 to 8 cents. Extracted, white, 7 1/2 to 7 3/4 cents; Amber, 6 1/2 to 7 cents. Beeswax, 20 1/2 to 21 cents, and sells on arrival. R. A. BURNETT & CO.

KANSAS CITY, July 7.—A small shipment of new comb honey on the market is selling at 14 1/2 to 15c. Good demand. C. C. CLEMONS & CO.

NEW YORK, June 9.—Demand good for extracted honey, all kinds, and same finds ready sale at the following prices: Fancy, 7 1/2 to 7 3/4c; choice, 6 1/2 to 6 3/4c; fair, 5 1/2 to 6c; common, 5 1/2 to 6c per gallon. Some demand for comb honey at from 11 1/2 to 12c for white, and 10c for amber. No more demand for dark. Beeswax dull at from 25 1/2 to 27c per pound, according to quality. HILDRETH & SEGELKEN.

SAN FRANCISCO, July 12.—White comb, 10 1/2 to 10 3/4c; amber, 7 1/2 to 9c. Extracted, white, 7 1/2 to 7 3/4c; light amber, 6 1/2 to 7c. Beeswax, 20 1/2 to 27c.

Only moderate quantities are arriving of either comb or extracted, with no prospect of the market being heavily burdened with offerings any time this season. Business is mostly of a jobbing character, and for such transactions the market is firm at the quotations. Some extracted of superior quality is arriving from Monterey County.

CLEVELAND, July 22.—Fancy white, 13 1/2 to 14c; No. 1 white, 12 1/2 to 13c; A No. 1 amber, 10 1/2 to 11c; No. 2 amber, 9 1/2 to 10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & CO.

BOSTON, May 17.—Fancy white, 12 1/2 to 13c; A No. 1 white, 11 1/2 to 12c; No. 1 amber, 9c; buckwheat, 8c. Extracted Florida, white, 7 1/2 to 8c; light amber, 6 1/2 to 7c. Beeswax, 27 1/2 to 28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is liked at this season of the year. BLAKE, SCOTT & LEE.

BUFFALO, Aug. 4.—The honey season has opened in a moderate way, a few small lots of new arriving. Extra fancy 1-pound combs, 13 1/2 to 14c; fair to good, 11 1/2 to 12c; dark, poor, etc., 8 1/2 to 9c. BATTERSON & CO.

OMAHA, July 18. Altho first receipts of new crop Southern honey were recorded early in June, there has not been any regularity about them since. A straggling lot of comb turns up now and then, and, when quality is choice to fancy, is eagerly picked up at 14 1/2 to 15c. A little lot of 1 1/2 lb crop was received a few days ago and went at 13 cents, quality not above choice. For extracted there is not such an urgent demand, still, 7 1/2 to 8c would be obtainable in a small way. The heavy buyers will hold back until later in the season, expecting to purchase on about the same basis of values as last year. Early shipments of all the comb that can be gotten out is certainly advisable; there will not be any chance of holding out with present quotations after the first demand is satisfied. PEVCKE BROS.

DETROIT, July 15. No old honey to quote, and no new offered. Prices are liable to rule higher as crop is short. The abundance of rain will no doubt help the crop of fall honey. Beeswax in good supply at 23 1/2 to 24c. M. H. HUNT & SON.

BEES QUEENS

Smokers, Sections, Comb Foundation and all Apiarian Supplies cheap. Send for FREE Catalogue. E. T. FLANAGAN, Bellefonte, Pa. 14A1y Please mention the Bee Journal.

M. H. HUNT & SON,
SELL ROOT'S GOODS AT ROOT'S PRICES. Shipping-Cases and Danz. Cartons are what you need to display and ship your honey in. Send for Catalog. BELL BRANCH, MICH. Please mention Bee Journal when writing.

Special Summer School of Shorthand

For the benefit of Teachers, Students, and others.
Six Weeks' Course for only \$15.00. Send for Catalog.

Eclectic Shorthand College,
Headquarters of the Cross Eclectic System,
518 Ashland Block, CHICAGO. 39A1y Please mention the Bee Journal.

I ARISE

To say to the readers of the BEE JOURNAL that

DOOLITTLE ...

has concluded to sell QUEENS in their season during 1899, at the following prices:

- 1 Untested Queen \$1.00
- 6 Untested Queens 4.50
- 12 Untested Queens 8.00
- 1 Tested Queen 1.50
- 3 Tested Queens 3.50
- 1 select tested queen 2.00
- 3 " " Queens 4.00
- Select Tested Queen, previous season's rearing, \$3; Extra Selected, for breeding, the very

best, \$5.00. About a pound of Bees in a 2-frame Nucleus, with any Queen, \$2.00 extra.

Circular free, giving full particulars regarding each class of Queens. Address, **G. M. DOOLITTLE,** 11A26t Borodino, Onondaga Co., N. Y. Please mention Bee Journal when writing

22nd Year Dadant's Foundation. 22nd Year

Why does it sell so well?

Because it has always given better satisfaction than any other. Because in 22 years there have not been any complaints, but thousands of compliments.

We guarantee satisfaction.

What more can anybody do? BEAUTY, PURITY, FIRMNESS, No SAGGING, No LOSS. PATENT WEED PROCESS SHEETING.

Send name for our Catalog, Samples of Foundation and Veil Material. We sell the best Veils, cotton or silk.

The following dealers handle our Foundation:

CARTONS

for Comb Honey. We use a superior grade of cardboard in our Cartons, altho we sell them as low as the dark strawboard ones are usually sold for. We make these for any size section in quantities of a M or more. Prices: \$4.50 a M on regular sizes; 5 M, \$3.80 a M. Sample mailed free. We furnish Cartons for the Ideal and Danz. sections, at regular prices.

A Bee-Veil

by mail, for 35 cents, with silk brussels front. If on receipt you are not satisfied with it, return it and we will refund your money.

Tested Italian Queens, 90 cents. Catalog of Apiarian Supplies free.

I. J. STRINGHAM, 105 Park Place, New York, N. Y.

Honey Wanted Any Quantity

If you have honey to dispose of, write us, stating the kind, quality, quantity, how put up, and the price wanted. If extracted, kindly send small sample when you write.

Address, **GEORGE W. YORK & CO,** 118 Michigan Street, CHICAGO, ILL.

CONTRIBUTED ARTICLES

A Successful Way to Sell Extracted Honey.

BY E. B. TYRRELL.

I SEND my promist report of success with my new method of selling extracted honey. In selling honey by this method, I have it put up in Mason quart fruit-cans, bearing my name and address on a highly-colored label, also another label containing directions for reliquefying.

Taking a number of cans so prepared, together with a sufficient number of circulars (of which I send a sample), I am prepared for my canvass.

On reaching my field of action, I distribute the honey and circulars around to the private houses, leaving a can of honey and one of each of the circulars, and on the following day, or the day spoken of in the small circular, I again call and collect what honey is not sold, and the pay for the rest. So far the plan has worked well, and I have lost no cans of honey, and I am positive I have made many sales where otherwise I would not have done so.

The benefits of this plan are as follows: Agents being considered by the majority as a common nuisance, nearly every one has "no" on the end of the tongue when anything is offered for sale by an agent, and the quickest way to get rid of him is the only thought, while many times, on reflection, people find they wish they had purchast. But this plan gets them from an unexpected quarter, "surprises the enemy," so to speak, and very few will deny you the privilege of leaving the honey; and once in a family (especially where there are children) the temptation to sample is too great to overcome, and if you have a good article a sale is made.

Again, this system dispels many doubts about its purity, for they reason that you would not leave it if it were not the genuine article, and, in fact, you wouldn't.

In practicing this system a strictly high-grade article must be handled, and you are establishing a future trade in honey. Genesee Co., Mich.

[The two circulars which Mr. Tyrrell mentions in the foregoing, read as follows:—EDITOR.]

[Circular No. 1.]

TO THE LADY OF THE HOUSE.

Knowing that when household or other duties are pressing, you do not wish to listen to the clatter of an agent, and not having the time to fully explain what the accompanying circular does, I leave you what I have to sell, together with an explanatory circular, which you will please read, and I will call again to-morrow, when you can either return the honey, should you not wish to purchase, or else the price of the can, 35 cents. If you will not be at home on the above day, please leave the honey or cash at one of your neighbors, and oblige,

Yours for trade,
E. B. TYRRELL.

[Circular No. 2.]

EXTRACTED HONEY.

Produced by - - E. B. TYRRELL.

TO THE PUBLIC.

Extracted honey is simply comb honey minus the comb. If you take a cake of comb honey, cut off the cappings or cover to the cells of honey, lay the cake in the bottom of a tin-pail, and then swing the pail around in a circle at arm's length, the honey on the side of the cake next to the bottom of the pail will be thrown out by centrifugal motion. Now turn the cake over, repeat the whirling process, and you have the comb emptied of its honey, and yet not destroyed. This liquid honey left in the pail is extracted honey. In the production of extracted honey by the bee-keepers, large combs are used, and the whirling is done by a machine or extractor, and the emptied combs are replaced in the hive for the bees to again fill with honey, when they are again extracted. As more honey can be gotten by this process, as the bees are saved the expense of building comb you can readily see why it can be sold cheaper than comb honey, and yet be just as good and pure in every respect.

Extracted honey will granulate or become white and hard in cold weather, and while at first this may seem to be a detriment, it is not, for it can be reduced to its liquid form again by simply heating it. Place the can or dish containing the honey you wish liquefied in warm water, when in a short time the honey will all melt, and will not granulate again for a long time, BUT BE SURE AND DO NOT LET THE WATER GET TOO HOT, not hotter than you can bear your hand in, as overheating the honey spoils the flavor and darkens it. I try to have all my honey in the liquid form when sold, but it may granulate in time after it is sold, and this is good, in fact the best, proof of its purity. Some prefer it in its candied or granulated form. Honey should be kept in a warm, dry place, dry especially, as freezing won't hurt it, but dampness will often cause it to sour.

In conclusion, I wish to say if there is anything you do not understand do not be afraid to ask questions, as I am building up a trade for my honey, and am willing, in fact wish, to answer all the questions you will ask me.

If you do not find my honey satisfactory, you need only drop me a card and I will call and take back the honey and refund your money. Is not that fair enough? My prices are as follows:

| | |
|---|------|
| One quart, or 3 pounds in a quart Mason fruit-jar | 35 |
| Ten pounds or under, per pound | 10 |
| Thirty pounds | 2 75 |
| Sixty pounds, or 5 gallons | 5 00 |

By buying 60 pounds you get it as cheap as maple syrup, or only \$1.00 per gallon. All honey sold by me (unless sold personally, direct to the consumer) bears my label containing my name and address. Remember, if you want honey at any time, simply drop me a card, and it will be promptly delivered at the above prices.

Yours respectfully, E. B. TYRRELL.

Care of Honey—It Needs Some Attention.

BY W. Z. HUTCHINSON.

AFTER honey has been thoroly ripened in the hive and is then removed, its future palatableness depends entirely upon the care that it receives. Too many look at honey as a simple sweet, like cane-sugar, forgetting that its flavor, its aroma, its "bouquet," so to speak, are its chief attraction, not knowing that exposure to the atmosphere will leave it a flat, stale sweet. The makers of maple syrup are careful to gather and boil the sap as quickly as possible, and then immediately seal the syrup. All this is done to prevent the loss of flavor by exposure to the air.

It is the same with honey. When first taken from the hives it has very distinctly the flavor of the flowers from which it was gathered. Each variety of blossom gives a distinctive flavor. By tasting of honey, an expert can very readily tell from what class of blossoms it was gathered. Sometimes the flavors are really too pronounced, too strong, when the honey is first gathered. Basswood honey is an example. In such cases a little exposure to the air may be an advantage. Thoroly ripened extracted honey should be at once put into bottles, cans or barrels and sealed up tight, and then put in a cool place. It will of course soon candy, or crystallize, but the flavor will be retained indefinitely, and the honey can be liquefied whenever it is needed for use. Care must be exercised in melting the honey, that the flavor is not injured by the application of too great heat. Of course the honey will not be burned if it is not heated hotter than boiling water, but the application of so great a heat as this rapidly drives off the flavor. Keeping the package closed and applying a very gentle heat—never above 150 degrees—is the better way. Putting up the honey in such packages as can easily be put into warm water, makes the liquefying more convenient.

Comb honey is of course already sealed, but not hermetically, unless it has remained on the hive a long time. Honey has a great affinity for moisture, and if comb honey is stored in a damp atmosphere, it will absorb the moisture thru the slightly porous cappings, and become thin and watery. The bulk of the honey will be so increast that it will burst the cells and ooze out. The honey may become so thinned that fermentation will set in. Cold is also detrimental to comb honey, causing it to candy in the cells. When comb honey is first taken from the hives, it should be stored in a hot, dry atmosphere. A room in the southwest corner of a building, where it will become very hot in the afternoon, is a good place to store comb honey. I know of one bee-keeper who has a small house of sheet-iron in

which to store his comb honey when taken from the hives. The heat continues the ripening process, and if there are any unsealed cells of honey, the honey in them becomes thicker and riper instead of thinner.

Down cellar is where the ordinary purchaser of comb honey is almost sure to put it. No place could be more undesirable. Dryness and warmth are the requisites for keeping comb honey. As ordinarily kept, comb honey will candy before spring; but by keeping it in a warm atmosphere it will not candy, and will really improve with time. I have now in my possession some comb honey that was on exhibition at the World's Fair, and it is still a first-class article. It has been kept in a cupboard adjoining the sitting-room. I also know of a bee-keeper who one year kept over a large crop of comb honey, because the price was so low. His honey-room was over a cellar, and the walls were double, with the spaces filled with sawdust. There was a stove in the room, and a little fire kept each day, the amount depending upon the weather. The honey came thru in good condition, and was sold the next spring at a considerable advance in price.

Several times in this article the "ripening" of the honey has been mentioned. I will explain that when nectar is gathered it is thin and watery. The heat of the hive, aided by the manipulations of the bees, gradually reduces the nectar to thick, "ripe" honey when it is sealed over. Some bee-keepers make the mistake of extracting honey before it is thoroughly ripened. Such honey never has a fine flavor, and is likely to ferment. Country Gentleman.

A Canadian View of Large and Small Hives.

BY C. MITCHELL.

I HAVE used both large and small hives side by side nearly 20 years, my largest being the D. A. Jones hive, which is 15 inches deep inside, and holds 12 frames running crosswise. It is the same size on top as the 8-frame Heddon hive. My other hive is the Heddon 8-frame Langstroth hive. For many years I have worked and twisted when reading the hot discussions on this subject, and wondered why every one seemed to have mist the most important point of all in the large hive, viz: that the large hive will winter more bees. In all those years Mr. Dadant is the only one I have noticed to even hint such a thing (until now).

The first season a swarm is put into a large hive it does not seem very profitable, unless there is a good fall flow, as it takes more honey to fill up the hive. But just as sure as death and taxes, they will carry over more bees, and consequently store more honey. I have often, when unpacking the first day of May, had to carry a knife and plate and take off two pounds of new honey under the cloth on top of the frames, while many of my 8-framers would not be full. How often has Mr. Dooittle said if he could only have plenty of field-bees at fruit-bloom that he thought he could get a good yield from it.

Now, where is the loss in a large hive? Perhaps it weighs 75 pounds with a class of honey which I hardly ever offer for sale—it is always willow and dandelion, and sometimes maple syrup. Red-squirrels have a way of tapping the twigs and letting the sap evaporate to a fine syrup, and the bees in good spells of weather find employment.

Then, often, we have a gap in the honey-flow for two weeks, just when there is the most brood—before clover when my 8-framers suffer much the worst. Now, what did this honey cost me? Not one cent more than the Heddon 8-frame, which hadn't any, and which is often empty by clover bloom, and which has to be filled up with white clover—just the very reverse of what is said on page 202.

No, no, Mr. Hutchinson, the above is not unwarranted with me. Of course, getting those occasional spring flows before we dare unpack, makes a difference, but I am tired of seeing so much of this begging locality for everything; also how much brood we can get from an 8-frame hive. I want at least one comb at each side without brood, which should contain fresh pollen and unsealed stores at all times up to the main flow.

I am satisfied I have lost hundreds of dollars by using 8-frame hives, in 15 years. I will hereafter have almost all of my bees in 10-frame hives, which will be my last change.

I even find no trouble in getting section honey from those large hives, but when they cast a swarm I prefer to put them into an 8-frame hive. Ontario, Canada.

Adaptability of Bee-Keeping to the Ministry.

BY HON. GEO. E. HILTON.

I HAVE often wondered why ministers did not engage in some light work, such as the raising of small fruits and vegetables, bee-keeping, or some of the health-giving, mind-resting, yet fascinating pursuits, thereby helping themselves to a little money aside from that received from their parishioners, leaving many times a better impression upon the community in which they live, and at the same time giving themselves that much needed mental rest. Every minister is familiar with Virgil and his beautiful poems, in which he wrote of the bee. Before the world had a Savior—yes, before the Christian era, bee-keeping was looked upon as one of the important industries of the Old World.

Our dear old Father Langstroth (now gone to his final reward), after losing his health in the ministry, resorted to bee-keeping with a hope of receiving a new lease of life. Bee-keeping at that time was in its infancy, and carried on in a very primitive manner. But his inventive mind and deep interest in the improvement of the old box-hive, gave us the movable-frame hive that bears his name. For this alone the bee-keepers of the world owe him a debt of gratitude they can never pay. He was the "Huber of America," and his name will be a household word wherever bee-keeping is known. As the result of his efforts, many ministers (whose names I can give) have engaged in bee-keeping in connection with their ministerial work, and I have often wondered what could be better adapted to those that have allowed their minds to delve into any special line of thought. All know how restful it is to have something that will divert the mind occasionally; no matter if the study is just as deep, the change is restful.

Another thing, I think the early and latter part of the day the better adapted to study and thought. As for myself, my best efforts in writing have occurred between three o'clock in the morning and daylight, when not another soul about the place was astir, and I think this is true with many. Now, the only time that bees need attention is during pleasant weather, and then only from eight o'clock in the morning until four in the afternoon. If a minister must be in his study during these hours, he can usually arrange his hives facing his study window, so that every time he raises his eyes for a moment's rest, they will rest upon the fronts of his hives. And what could be more restful than to watch for a few moments those "tireless little workers" and "emblems of industry"?

Many will ask, What will I do with them Sundays? Or won't they, the first time I have a funeral to attend or a marriage ceremony to perform, think it about time to increase and swarm and go to the woods? In reply I will say, scientific apiculture has overcome these obstacles, and by placing any of the queen-excluding devices over the entrance, the swarm is safe. This will not prevent their swarming, but as the queen cannot escape, as soon as the swarm miss her, they will return to the parent colony, and, as a rule, will make another effort the next day. But I usually save them this trouble by going to the hive and removing all the combs with adhering bees, except the comb I find the queen upon, to a new hive, and fill up this hive with empty combs or frames, well wired and filled with full sheets of foundation. All the old or field-bees will return to the parent hive the first time they leave the new hive, but the nurse-bees, or those less than ten days old, will remain in the new hive and care for the brood and rear a young queen, and both colonies will build up rapidly. As the swarming season lasts only about two months, this is not much trouble. Or, you can manage your bees for extracted honey, and you will not average one swarm from ten colonies.

There are many other points I could enumerate, but to those who are apiculturally inclined, I have said enough. So far as I know, it has proven fascinating, healthful and profitable. —Michigan Farmer.

Density of Nectar in the Flower-Cups.

BY A. B. BATES.

MR. NORTON, on page 403, in unraveling the idea of different densities of nectar in the flower-cups, says that nectar when first secreted is of a uniform consistency. Doubtless true, and when God made man he pronounced him not only good, but very good, but how was he afterwards? Is there not a possibility of nectar changing

from that state of evenness it was secreted by the flower-cup that would bring about the facts as I have expressed them in my former communications?

It is an admitted fact that honey in ripening thickens: this admitted, it follows logically that the honey of the same cell and at the same time, during its process of ripening, is of different densities, and if such characterizes honey in the cell, why is not nectar in the flower-cup subjected to the same changes, admissive of the same characteristics under like circumstances?

According to the theory that warm air contains more moisture than cold air, honey kept in a warm, airy department gives off moisture: the cool air entering a warm room, or better, a warm hive, where honey is stored, takes up moisture; coming in contact with warm honey it expands, and takes on moisture. On the other hand, if it is stored in a cold, damp cellar, the warm air from without, striking the cold honey within, contracts and gives off moisture. And since honey must become tangible to the air before its moisture can be absorbed by it; and since the atmosphere cannot penetrate the wax of the cell to be tangible to all parts at the same time, it follows that the watery or thinner part of the honey must be drawn to the mouth of the cell, constituting not only a difference in the density of the honey of the cell, but leaving the richer of the saccharine substance at the rear. So attraction as well as gravitation testifies in behalf of my statement.

And what is true of unripe honey is also true of nectar, since it is rawer, more easily affected, and admissive of changes.

The earth's surface at night retains the heat received from the sun longer than the atmosphere above it; the cold air coming in contact with the warm objects—flowers as well as other things—contracts, giving off moisture, pouring it into the flower-cup on top of the nectar, and it will have to be proven that water is heavier than nectar, or else we have nectar in that cup not of a uniform thickness and sweetness.

Suppose the short-tongue bee can barely reach to the nectar in the cup without any margin to go on; when the moisture of the atmosphere is poured in on this nectar till the cup is filled to the reach of the short-tongue bee, and surplus is stored, what is it? Sweetened water. Is there nothing better remaining in the flowers from which this was stored for a longer-tongue strain?

I have observed distinctly on many occasions my Italian bees working early in the morning on red clover. If they are not extracting the sweetened moisture resting on its nectar, why not work on it as freely at other hours of the day?

I cannot exactly understand Mr. Norton's meaning of the word "far-fetched," and in conclusion will say his lime was too much saturated; if he places together the proper measure of parts, he will form a body we call "mortar," that compares to fully ripened honey, equal in density and sweetness.

Franklin Co., Mo.

The Bee-Business and Prospects in Utah.

MR. J. S. SCOTT, of Utah Co., Utah, wrote us, July 23, in reference to the present condition of the bee and honey business in Utah:

EDITOR YORK:—

My object in sending you the enclosed letters is that the facts may be known regarding the condition of the bee-business and prospects for a honey crop in Utah. The letters are from prominent bee-keepers in four of the principal honey counties in the State, and can be relied upon as to the true condition.

The loss in bees here is about 50 percent. Those left are doing but little. Utah will not have half a crop of honey.

I sent out the questions found in the enclosed letters, and received the answers, which explain the situation correctly. A certain Salt Lake City bee-keeper wrote a letter to a bee-paper in which he stated that the loss of bees was about 10 percent. Such reports are injurious. Had he taken pains to ascertain the truth, he certainly would not have made such a mistake.

J. S. SCOTT.

The questions which Mr. Scott sent out read as follows:

1. What is the prospect for a honey crop in your vicinity this season?
2. What is the percent of loss in bees?
3. Did greater mortality occur during winter or spring?

4. Do your bee-keepers produce more extracted than comb honey?

5. What, in your opinion, is the prospect for a honey crop throughout the country?

The responses received are given here, using as a signature the county from which the replies came rather than the name of the bee-keeper, as requested by Mr. Scott:

1. Rather poor outlook. Half to two-thirds crop.
2. About 50 percent loss, from trustworthy reports.
3. Winter killed and weakened so many that it was more severe than spring. Greater mortality in winter.
4. Salt Lake County produces more extracted honey.
5. Much less than an average; about two-thirds, for an estimate.

SALT LAKE.

1. The prospects are very poor.
 2. I should judge about 40 percent from all causes—winter loss, spring dwindling and foul brood.
 3. During spring.
 4. Mostly extracted.
 5. The prospects for a honey crop are very poor.
- The bee-inspector reports a great deal of foul brood, some apiaries with every colony diseased. The trouble has been, dying in winter and letting them get robbed out.

UTAH.

1. Good where the bees are in good condition. Crop will not be large.
2. From 10 to 100 percent. Mine is about 80 percent. A good many that are left will only build up for winter.
3. Spring.
4. No. All comb honey.
5. I think the honey crop will be small, for lack of bees to gather it. I have 48 colonies left, from 170 taken out of the house in what I thought was fair condition. It is too early to be sure, yet where the bees are strong I think they will do well. I have 35 colonies that will be all right. I have not had any swarms yet. What is the matter that so many bees have died the past winter and spring? Mine did not die; they left. I think it was because they could not get any pollen. I do not think it was cold weather alone that killed the bees, but the frost killed the flowers here and the bees left.

WASATCH.

1. Fair, tho rather early to speak.
2. About 33 1/2 percent.
3. Spring.
4. Extracted.
5. I am not posted on conditions about the county.

As there was nothing to indicate from what county the last replies came, we were compelled to leave them unsigned.

The "Old Reliable" seen through New and Unreliable Glasses.
By "COGITATOR."

A MICE-KILLING BUG.

"Bugs, such as mice," eh? Page 405. Well, it's fair strategy to make one kind of bug kill another kind; and they claim to have a bug now that will kill mice.

QUEEN-CELLS BUILT BY RECENT SWARM.

Thanks to Dr. Miller for his suggestion that queen-cells built by a recent swarm are not rare but common. Guess he's right. Page 406.

WELCOME TO HAND-SHAKING GLOVES.

Yes, Dr. Peiro, I'll be good now: so kind a reply to an irreverent, if not irrelevant, racket compels it. Hurrah for the hand-shaking gloves! A fellow must be *kind-o'* good when he hurrahs for them, must he not? Page 478.

NEW-OLD BEE-LITERATURE—LARGE VS. SMALL HIVES.

Mrs. Woodmansee very wisely thinks that many things which we read carelessly the first time are new when we

read them again. It is also true that many things a beginner cannot digest will be interesting and nourishing a year or two later on. Keep your bee-magazines and see how meaty they will seem on second reading. She made a good spring observation as she watcht that apiary being overhauled. Eight-framers and sectional hives all very weak; ten-framers much better; tens and twelves with big and extra-deep frames mostly rousers. Something may have to be done about this if it is *always* so. Will take some time to decide whether it is or not. Page 418.

ALWAYS WRITING WHAT ONE MEANS.

Dr. Miller gets at the root of an important and vexatious matter where he says writers sometimes say something quite different from what they mean. Page 418. As a sort of corollary of this suffer me to say that few (I suspect) get to be writers of the very highest rank till they contract a sort of frantic dislike for sentences and clauses that *can be* understood in more than one way. Even if laziness does say, "Let it go; no one will ever misunderstand *that*," out it has to come.

FINE LOT OF BEE-STING REMEDIES.

What a fine lot of sting remedies C. P. Dadant enumerates on page 419! Some got away, too. I think we may profitably talk a little more about *rubbing* as a sting remedy. Altho pretty sure to make ordinary patients worse, it is handy, and really excellent, for bee-keepers who have become two-thirds inured to bee-poison. Remove the sting instantly, and rub the spot until it burns (with frictional heat) so you can hardly bear any more; then go on with what you're at, and avoid thinking of or looking at the sting at all, and the poison will be so diluted and spread around as to fail to set up its characteristic action. Pretty much the same may be said of opening the smoker door and toasting the spot. That we lose part of our inurement every winter, and gradually recover it when we begin handling bees in spring, is a rather unfamiliar idea to my noddle, but quite likely it is right.

AMMONIA AND CLOSING THE PORES FOR BEE-STINGS.

Mr. Dadant ventures on the record that the very best remedy of all is ammonia—external for moderate cases, and internal also for worse ones. I will venture that the very best remedy is closing the pores of the skin in the vicinity of the puncture. Sting analogous to a fire, and this remedy is like shutting the doors and windows. *How* to best close the pores decidedly depends. If the sting is on clear, level territory (mostly it isn't) the best way is to put on three or four inches square of tissue paper with strong mucilage. If it's near the holes and hummocks of the countenance, smear a similar extent of space with the thickest honey you can get, or with any harmless and viscid substance. Get rid of the idea that the daub effects any chemical or medical change, and understand it as merely keeping away part of the natural supply of oxygen. Page 419.

BEE-STING INFORMATION—"IMPORTANT IF TRUE."

Never saw so much bee-sting information in one place before as in the bee-boil from J. Langer, on page 437. Important if reliable. We can all test this scientist's work at one point, where he says the poison has a *pleasant* aromatic odor. To be sure, the smell that one person likes another don't like, but some of us would say *unpleasant*. A mere trifle heavier than water. From 166 to 333 bees carry a grain of poison. (Looks exaggerated. A grain would be quite a lot.) The poison proper is not the acid itself, but dissolved in the acid—and precipitated by alkali. Then what earthly use to give ammonia, or other alkali, as a remedy? The dried poison is as poison as ever; but left in its natural fluid state, and in a glass tube not sealed, it becomes harmless in about four weeks. Sealed it keeps longer. Here's richness and wisdom, lots of it—if somebody else doesn't come and upset it all. Simmer the above and Dadant's article well together—the resulting elixir well shaken before being taken.

NEW EDITION OF DR. WATTS' "HIMS."

So according to Dr. Watts (page 419) *Apis dorsata* build but one size of cell, and their drones are all reared in worker-comb. Small edition of Dr. Watts' *hims*!

OPEN-AIR HONEY LIABLE TO FERMENT.

The idea that all varieties of bees which build in the open air trust to aerial evaporation to keep their honey, and do little to it themselves, is striking, and impresses one as likely to turn out correct. That nearly all of 60 or 70 honey

samples at Calcutta fermented more or less, looks like pretty good evidence.

DOOLITTLE'S EXPERIENCES.

The Doolittle article, page 420, may be summed up in this: Don't give a laying queen to a colony that has just swarmed, unless your rather exceptional location yields a continuous flow. Tater (without feeling sure) would incline to say: Don't do it at all—makes the swarming worse, which is likely to be terribly bad without. Mr. D.'s experience hardly covers that kind of a location, I think. Thanks for the able way which he has workt up what he has experienced. Hope he will tolerate my good, hearty dissent to his doctrine, that bees reared during basswood are mostly dead before fall-flower harvest. Say *might be*, so far as time goes, but as midsummer is apt to be largely idle time, more frequently in first-rate working order.

BEEES WORKING ON PEAS—COWPEAS?

And W. T. Lewis, on page 431, we'll nail him to the record as one who has seen bees work with enthusiasm on peas. May be he means cowpeas, however, which would be less remarkable.

DRONE-COMB IN THE SECTIONS.

Three respondents, on page 427, intimate that drone-comb in sections is no harm. Tater thinks the harm of it has been greatly exaggerated.

WHITE VS. BLACK POULTRY.

And Tater wants to put one of his bugs in the ear of that poultry-man, page 425, who took to light-colored fowls because his bees worried the dark ones. Doesn't he know that standard works on poultry favor that change for an important and entirely different reason? Fowls have to be killed and sold, even if eggs are the main object, and white ones look and sell better when drest.

PERHAPS A MIX-UP OF FIGURES AS WELL AS SWARMS.

It's a nice one—that record on page 422, of 548 swarms from 48 colonies in one year—else a mix-up of figures, or something. That is over 11 swarms to one count in spring. As Mr. Dadant (Gleanings in Bee-Culture 460) speaks of it as *seven* per colony, probably there has been some slip.

THAT CURIOUS RESULT FROM SCRAPING HIVES.

Just to be contrary, I'll guess that that doubted experience on page 441 was genuine. Bees had been gathering, as substitute for propolis, some sticky and very poisonous paint.

ILLINOIS' PURE FOOD COMMISSIONER.

Gov. Tanner's reasons for not appointing a dairyman or bee-man as food commissioner *sound* all right. Must be thankful that a glucose man or oleo man was not wormed in somehow. Page 440.

IS SWEET CLOVER HONEY DARK?

Rather a novel idea to us that sweet clover is a dark honey—still not necessarily an error on the part of that Kansas official, on page 440. Liable to be blackened by mixture with road-dust, one would say. And most of us do not see sweet clover honey unmixt with something else.

BAIT FOR HUNTING BEES IN TREES DURING A HONEY-FLOW.

I fear Mr. L. J. Clark, page 446, will not find the bait that bees will work on zealously while the nectar harvest is good—

Quoth the sagacious little bee,
"The best is good enough for me"—

and therefore the tempters will tempt in vain. But there are often periods of a week or more in summer when the flowers don't "give down." Watch an apiary till you capture one of these famine spells (when domestic bees are inquisitive, and eager for anything that turns up), then go for the woods with the usual device of burning comb and exposing honey. I can see no reason why some success might not be had in any season when bees will rob.

PUTTING SMOKER-FUEL ON TOP OF THE FIRE.

Mr. C. P. Dadant uses poor smoker-fuel, I plainly see—with first-class fuel it is a very bad plan to put it on top of the fire—burns up too quick. All the same, his talk to beginners (page 434) is an excellent one. COGITATOR.

The Premium offered on page 525 is well worth working for. Look at it.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

Hardly Foul Brood.

I opened the hive of one of my best colonies yesterday, and found about a dozen dead larvæ about ready to cap over, some were white, some of natural color, others were all settled back in the cell. Part were a little rosy, without any smell to any of them. I opened other hives, and found now and then a dead larva, probably four or five on some frames. On the frame that had the most dead, a worm that look like a wire-worm crawled out of the comb. It wasn't a moth-worm, for it was very slim. I thought it might have something to do with the case.

MINNESOTA.

ANSWER. Your bees hardly have foul brood, but it will do no harm to watch the matter closely. I don't know what that worm may be, and don't know whether it has anything to do with the trouble.

Queen-Rearing Questions.

1. Do you think that it will pay me to rear queens next year?
2. Please give the best method you know for queen-rearing, and explain it.
3. How many queens do you suppose I would sell in one season?
4. How many nuclei should I have?
5. What mailing-cage is the best? SOUTH CAROLINA.

ANSWERS. 1. Doubtful that it will pay you to rear more than enough for your own use, unless you have had a great deal of experience.

2. Get Doolittle's book on queen-rearing and study it up in full.

3. Probably very few the first season. A great many are selling queens, many of them well known for years, and you would stand rather a poor chance as a stranger.

4. That would depend altogether on the amount of your business. If you expect to sell 10 a month, you would perhaps need that number of nuclei.

5. Perhaps the Benton cage.

A Number of Queens and Queen-Cells in a Colony.

I had an experience the other day that far surpasses anything I ever saw, or anything I ever read, tho I will confess that my experience with bees has been very limited.

In June I discovered a colony of bees in a tree, out in the woods. Not long ago I cut the tree, and brought home that part of the trunk that contained the bees. July 21 this colony swarmed; after hiving them, I made an attempt to find out what caused them to swarm. Upon investigation I discovered a piece of comb in the trunk of the tree (after splitting it open), about one foot square, that contained 23 queen-cells; and upon further investigation I discovered 10 queens, all alive, that were left in the tree, and I do not know how many queens are with the colony now. This incident seems to me to be a very remarkable one. It seems to abolish, and upset, the theory of but one queen to a colony.

As I have said, my experience has been very limited, and this incident may be a usual occurrence. This colony had just located in the tree last spring.

ILLINOIS.

ANSWER. The rule that only one queen is suffered in a hive is subject to exceptions. It is not so very unusual to find two queens laying in the hive at the same time, a mother and a daughter, the mother being about played out. There are also rare cases in which two queens, not related will be laying in a hive at the same time. But to find a

number of virgin queens in a hive at certain times is the rule rather than the exception. A number of queen-cells are started when bees contemplate swarming, and about the time the first one is capt over the prime swarm issues. Something like eight days later the first young queen emerges from her cell, and if the bees have it in their plans to swarm further, no other queen is allowed to issue from her cell till the issue of a second swarm. It often happens that when all idea of swarming is given up, all the queens that are mature enough are allowed to emerge from their cells, as in the case you saw. But there will not long be more than one of them in the hive, for they will fight till only one is left.

A Colony Continually Swarming.

We bought a colony of bees June 4, and about three weeks ago they swarmed. We caught the queen in the trap, and that night I gave them two full frames of brood and two frames already drawn, and filled the rest of the hive with frames and foundation, and ever since they have been swarming once and twice a day. We were very particular in scraping the hive and scalding it out with salt water, so we put them in another hive and gave them a new bottom-board, and still they are the same. They are carrying a little pollen in, but we cannot see they are doing much more. The swarm we got June 4 swarmed again July 23, and they are working very hard.

ONTARIO.

ANSWER. It is quite possible that the two frames of brood are more than they desire, making it seem too much as if they were still in their old hive. If you leave them with no brood or honey they may change their minds.

Feeding for Winter Stores.

This year is a very poor one for bee-keepers in this section of Iowa. Spring opened three weeks later than the average of the past 10 years, but then the continuous warm weather soon made up for the time lost, the trees blooming as early, if not earlier than usual, and colonies that had suffered from the long-continued cold winter did not have time to build up to take full advantage of it. After fruit-bloom the bees were in very good condition, and by the time the wild cherries bloomed many were so populous that extra extracting-supers had to be put on to prevent crowding the brood-nest by the honey coming in. This caused the bees to swarm as early as May 23, and possibly sooner in other places. The honey-flow, however, was cut short by heavy rains and storms. Raspberry yielded some; basswood failed; white clover was winter-killed, yet an abundance of it has grown up, which is promising for next year. Basswood and white clover are what we mostly depend upon for surplus, and golden-rod frequently yields a fair crop in the fall.

Until now, the bees could use up all they could gather, and, unless the fall flowers yield sufficient, we shall not have any surplus this year, and may be compelled to feed our bees for winter. I would like to ask for advice, in that case.

Would you advise feeding sugar syrup, or the cakes recommended by Mr. Abbott? How would you make these cakes, and of what size?

IOWA COUNTY.

ANSWER. The candy cakes are for winter use, and the syrup is the thing for you to feed while the bees are flying. It is true, Mr. Abbott thinks highly of a cake of candy over the frames as a matter of security, but I think he would not want the whole of the winter stores in that shape. Neither would I feed syrup, strictly speaking, but sugar and water, without any cooking. Feed equal parts of sugar and water, either by measure or by weight. The water may be hot or cold. Feed in any way that allows the water to drain down thru the sugar. The Miller feeder is good for this sort of feeding, and so is the crock-and-plate plan. But the feeding must be done early enough so that the bees can properly ripen it. Better get thru with it as early in September as you can, or even in August.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Amount of Wax from Brood-Combs.—Editor Holtermann says in the Canadian Bee Journal: "F. A. Gemmill says in the Bee-Keepers' Review that the amount of wax he has been able to secure from a set of 8 Langstroth combs is 3 pounds. I will guarantee I can take 8 Langstroth combs and get 4 pounds of wax from them."

Surplus Honey in Frames.—Mention is made in the British Bee Journal of a plan of producing combhoney that was introduced by R. A. H. Grimshaw. Shallow frames of foundation are taken to the moors, the frames being wired. When it is desired to make use of the long slab of honey on the table, the wire is clipped from its fastening and drawn out endwise.

Keeping Comb Honey.—G. W. Demaree says in Barnum's Midland Farmer that he has a few sample boxes of comb honey two years old with cappings as white and pure as when taken from the bees, and such honey can be kept in this condition for an indefinite time if kept in a warm, dry room. If chunk-honey must be packed in crocks, set the combs on edge, and when filled within a few inches of the top, cover with extracted honey.

Solar Wax-Extracting.—W. R. N., in the British Bee Journal, says he has found it advantageous, instead of placing in his solar wax-extractor the material to be melted directly upon the perforated bottom of the tray, to put first on this some very thin and cheap cloth, and then when it comes time to clean out, this cloth can very easily be peeled out while the heat is present. He thinks well of going still farther and having only the cloth, then it can be thrown away as often as it becomes clogged.

Apis Dorsata.—Here's what Editor Holtermann, of the Canadian Bee Journal, thinks about it: "I cannot imagine that we want a bee which can rear drones and workers in the same cells. We can control drones in *Apis mellifera* with comb foundation, surely no intelligent and well posted bee-keeper would go back to the system where he cannot control drones by using worker-comb foundation. It is well to investigate, but the more I hear of the bees the less favorably I am impressed with their economic value."

The Source of Honey-Dew is discussed in an interesting manner by R. McKnight in the Bee-Keepers' Review. He greatly disagrees with Prof. Cook, who thinks all honey-dew is the production of aphides. The honey-dew seems to be much the same thing as the nectar of the flower, only found in a different place. He speaks of the change of material into starch, then into sugar, and then into woody tissue, and says:

"From the saccharine stage of digestion comes our honey and honey-dew. The former is in some manner, as yet unexplained, determined to the flower, while the latter is the result of the sap-cells, under certain atmospheric conditions, becoming gorged, when a portion of the sweet juice they contain exudes thru the pores of the leaf and green shoot, and rests on their surfaces—hence our honey-dew."

Weed Foundation.—C. Davenport, in Gleanings in Bee-Culture, says that after making most of his foundation for years he shall probably buy instead of make in the future. The great difference between the price of wax and foundation is more than offset by the amount of work in rigging up, properly purifying the wax and making into foundation. For bottom starters he has found the Weed much better than his own, and in one case he gave it a very severe test. He put small, three-cornered starters at the top, and at the bottom about as narrow starters as could be fastened with a Daisy machine, and not six out of a thousand failed of being accepted, drawn out, and fastened to the upper one as soon as it was built down low enough. The severe point in the test was that this was at a time when the flow was scant and irregular.

This certainly shows superiority in the Weed founda-

tion, for with the older kinds there was complaint that when the bottom starter was thin it would topple over or be gnawed down by the bees, unless the top starter came close down and there was a fair flow of honey. The A. I. Root Co. say they can now furnish in quantity the Weed foundation running 18 feet to the pound with fair sidewalls, and if this will be used by the bees without being gnawed in a scant flow, and will stand up when used for bottom starters, there surely ought to be no more trouble about "fish-bone."

Bee-Paralysis in the South is a very serious matter, much more serious than Northern bee-keepers are likely to imagine, for in the North it amounts to very little. In the South, Editor Root thinks it may be even worse than foul brood, two bee-keepers to his knowledge having been driven out of the business by its ravages. O. O. Poppleton, of Florida, says in Gleanings in Bee-Culture that he can cure it, but at the expense of any income from the colony for the season. In a number of cases Mr. Poppleton has found the daughters of purchased queens to give the disease to their colonies, altho the colonies of the mothers may have remained healthy. The queens were obtained from reliable men, and he has no idea that paralysis was suspected by the sellers, even if it existed.

Bees Photograph in Glass Hives is the heading of an article in the Canadian Bee Journal copied from the Buffalo Courier. It gives a somewhat detailed account of observations to be made (by whom is not mentioned), deciding unsolved problems about bees. Among other things, when a bee leaves the hive, it passes thru a vestibule where its weight is accurately determined, "a delicate mechanism" marks the bee with color, and on its return its weight is again taken to measure its load. Just how much dependence may be put in the whole affair may perhaps be judged from the somewhat amusing statement that one of the things to be studied is "the curious method by which the bees are enabled to 'construct' queen-eggs when the regular queen-eggs have been destroyed and there is no resident queen to lay others." How's that?

Covering for Hive-Roofs.—J. A. Green has reported very favorably as to the use of corrugated sheet-iron over his hive-covers. On this matter a writer in the British Bee Journal says: "I note that the question of the advisability of using thin zinc as a covering for hive roofs has been raised both in the Bee Journal and Record. If your correspondents mean a wood-roof covered with zinc laid close down, and turned in at corners and edges, let me say I adopted that plan, and my experience is that roofs so covered prevent rain entering from the outside, but, owing probably to the continual condensation of moisture, these roofs were always damp inside, altho in my case they have the usual ventilating holes fore and aft. To avoid this fault, I last summer covered the roofs of two hives with cuttings of corrugated-iron roofing, simply laying them loose on top and weighting down. In March last both roofs were quite dry.

"If we could get thin galvanized iron (say 24-gauge) with small corrugations, I think it would answer well, as it is the want of free circulation of air beneath the zinc that causes dampness, and this is obviated by the use of corrugated iron."

Drone-Cells vs. Doolittle Cups.—Editor Root having said, "without artificial cups nothing could be done," W. C. Gathright replies in Gleanings in Bee-Culture:

"I have been rearing cells by the Doolittle plan for three years, in upper and lower stories, with the laying queen in the hive all the time. I have not made an artificial cell for two years, and would not think of going back to that plan. I use strips of drone-comb with the cells cut down half depth, and place a larva in every other cell. This gives room to cut them apart. I often get every cell accepted, and as many as 22, tho I destroy all but about 12 or 15. I make a frame with top-bar and ends only 1/2-inch wide, and do not put on a bottom-bar, but put in a bar about 3/8 square, half way between the bottom and top. This middle bar is to fasten the strips of drone-comb to.

"I next cut my drone-comb in strips about 3/8 wide and 4 inches long. I use three pieces for each frame. To fasten them to the bar I use melted wax. I dip each piece into the wax, first letting the edge of one side touch the wax, when it is placed on the bar, and it is fast perfectly solid in a moment. I can fasten a strip of drone-comb in the same time it would take to fasten one artificial cup."

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee—\$1.00 per Annum.**EXECUTIVE COMMITTEE**—Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.**BOARD OF DIRECTORS**—E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.**GEN'L MANAGER AND TREASURER**—Eugene Secor, Forest City, Iowa.**Place and Date of Next Meeting:**

IN FRANKLIN INSTITUTE,

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39. AUGUST 17, 1899. NO. 33

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

Why Take a Bee-Paper?—The editor of Bee-Chat having asked for reasons for taking a bee-paper, one of his correspondents replied:

- "1. Because it keeps me abreast of the times.
- "2. Because by enquiry in its columns I can get information on any unusual difficulty that may arise in my apiary.
- "3. Because I can help to provide the editor not only with the sinews of war by my subscription, but also add to his moral support by increasing his clientele."

There is every reason why a bee-keeper should read a good bee-paper, while there is likely no reason why he should not. How any one can expect to be successful with bees, and not read the best current bee-literature is beyond our comprehension.

Correspondents of Bee-Papers. Referring to an editorial in these pages as to the smaller number who write for the bee-papers nowadays, Editor Root, of Gleanings in Bee-Culture, says bee-papers are run for the benefit of subscribers and not correspondents; so the editor must get the best he can, and, as many of the best bee-keepers either have not the faculty or have not the inclination to write what they know, the number of writers has become limited, and it is the business of the editor to keep the few who do write from running their followers into ruts.

Per contra, a writer in the American Bee-Keeper asks

that a page be set apart for amateurs, and the editor announces that a department will be started for amateurs as soon as material enough comes to hand for it, all intended for it being marked by the writer. "Amateur Department." This will relieve the editor from the delicate task of sorting out the amateurs from the others.

While amateurs are fully represented in the American Bee Journal, they are allowed to mix in freely with the rest of the family.

The Chapman Honey-Plant is still talked of as a valuable new thing in some of the foreign bee-journals. Is there any one in this country who continues to believe it worth cultivating?

Bee-Keeping a Studious Occupation.—G. W. Demaree says in his department in Barnum's Midland Farmer, that facts show that there are more failures in bee-keeping than in other domestic pursuits. He thinks the reason is that it requires closer study and greater skill to handle bees profitably than most bee-keepers are willing to afford. The most successful bee-keepers are those who have a natural taste for the study of insect life, with some inclination toward botany.

The Honey Market.—Quotations have held up pretty stiffly thruout the past year, but at present they hardly seem in proportion to the scarcity of honey that reports indicate. Editor Root says in Gleanings in Bee-Culture:

"From present indications the season over the country generally will be even poorer than that of last year, and we thought 1898 was about as poor as it could be. Comb honey—at least a choice article—ought to be sold at a higher price than it has sold for for several years past."

But the commission men and dealers make quotations that show no advance in price. Are they doing the right thing by their clients?

Advertising the United States Bee-Keepers' Association.—Editor Holtermann, of the Canadian Bee Journal, endorses what H. F. Moore has said in the American Bee Journal about keeping the craft fully informed as to what the United States Bee-Keepers' Association is doing; but he does not agree that it would be a good plan to have the manager or secretary of the association send copy to one bee-paper with the request that the others copy. Mr. Holtermann wisely suggests that the better plan would be to send to all bee-papers at the time when most of them would be ready for copy. A bee-paper would be more interested to publish information sent to it direct, even if all others were to have the same matter, than to copy that matter after it had been printed in some other paper.

Success Thru Reading and Thinking. Prof. D. H. Otis, of the Kansas State Agricultural College, gives some excellent hints in the following paragraphs:

Among the questions asked of creamery patrons by the Kansas Experiment Station is, "What dairy or farm paper do you read?" Out of 77 patrons who answered this question we found that 53 (or 69 percent) took no farm or dairy paper. In looking up the details of the records it is interesting to note that the highest yield was made by a man who keeps special dairy cows and subscribes for a dairy paper. This patron realized \$9.00 per cow per annum more than the next best patron who reads no paper, and \$36 per cow more than the poorest patron.

In collecting records from various parts of the State we find where intelligence is applied to the dairy industry the cow is yielding from \$60 to \$80 worth of dairy products per annum. Contrast this with \$20 to \$30 without intelligence and no one need ask if education pays. At the Kansas Experiment Station we find that intelligence applied to feeding calves will cause them to gain from 12 to 23 pounds per

week instead of 7 to 10 pounds. This is an age when intelligence can be turned into cash, when, as Secretary Coburn says, "Muscle to win must be lubricated with brains."

D. H. Otis.

Some one asks, "Well, what has that to do with bee-keeping"? We answer, everything. Why shouldn't intelligence and brains, when applied to the care of bees and the production of honey, be equally successful?

We feel sorry for the bee-keeper who takes and reads no paper devoted to bee-culture. He stands right in his own light, and cannot possibly hope to compete successfully with the bee-keeper who reads and studies, and then uses his increased intelligence in conducting the apiary. This is an age when to be able to compete in the struggle for an existence and subsistence, a man needs to avail himself of every advantage possible, and nothing can be more helpful in the race for success than a good supply of intelligence properly applied.

"Buckwheaters" and Grading.—An interesting conversation between Editor E. R. Root and Mr. S. A. Niver was taken down in shorthand, and is reproduced in *Gleanings in Bee-Culture*. "Buckwheaters," as Mr. Niver calls those who have large crops of buckwheat honey, as many do in New York State, have conditions quite different from others. Bees usually go into winter quarters "loaded clear to the brim" with buckwheat honey. From the time of soft maple in the spring there is always something coming in, so that if a colony dies in winter its combs of honey are not needed to supply other colonies, and being extra-ripe and good may be extracted. Mr. Coggshall extracted 3,000 pounds of such honey from colonies that died the past winter.

Grading was discussed, Mr. Niver not agreeing with Mr. Root that there ought to be a special grade for sections filled out clear to the wood. He thought it would only confuse, the amount being so small, and advised that such honey be eaten at home, altho he thought a section really nicer that had no honey in the outside row of cells. To get sections filled and sealed clear to the wood requires that the bees be so crowded that such sections will cost more than the extra price that can be obtained for them.

The Honey Season in Canada seems poor as well as on this side the line. The *Canadian Bee Journal* says:

"The Canadian crop has not been all harvested; frequent showers may give a good deal of thistle honey, but so far the clover honey crop has not been up to expectations; conditions seemed to be all favorable, but did not pan out."

The editor thinks no one need to sacrifice his honey crop in order to dispose of it.

York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 70 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the *American Bee Journal* should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the *Bee Journal* for a year—both for only \$2.00.

The Philadelphia Convention, to be held Sept. 5, 6 and 7, in Franklin Institute, 15 South 7th Street, between Market and Chestnut Sts., promises to be the best ever held by the United States Bee-Keepers' Association, if we may judge by the excellent program arranged for the occasion. Also in view of the low railroad rates guaranteed to every one going to

Philadelphia, Sept. 1 to 4 inclusive, there should be a very large attendance. The editor of the *American Bee Journal* and Dr. C. C. Miller, with other bee-keepers, will go over the Pennsylvania Lines, beautiful illustrations of whose entrancing scenery and elegantly equip coaches we have the pleasure of showing on our first page this week. Without doubt the Pennsylvania Lines run thru the finest country for scenic beauty to be found in all the East.

The Grand Army of the Republic holds its 33rd annual meeting in Philadelphia, Sept. 4 to 9, inclusive. Many bee-keepers are also old soldiers, and likely members of that splendid national organization of war veterans; all such, as well as other bee-keepers, should take advantage of the low rates secured by the G. A. R. people, and be in Philadelphia during the week of the Grand Army meeting and the bee-keepers' convention. The round-trip rate from Chicago, over the Pennsylvania Lines, is only \$16.45. That means you will be given a ride of 1,645 miles.

The Grand Army Encampment will be noteworthy in many ways. It is expected to be the largest ever held. For the first time since the occurrence of the events which gave birth to the Grand Army of the Republic, the Stars and Stripes have again been carried to victory, and the fire of patriotism again burns with a bright and steady flame which will induce many veterans, their families and friends, to attend this annual reunion.

Extensive arrangements are being made for the entertainment of visitors to the City of Brotherly Love on this occasion, and the exercises will be of unusual interest.

The festivities of the week will be inaugurated by a parade of Naval Veterans on Monday, Sept. 4. The grand parade of members of the Grand Army of the Republic will occur on Tuesday, Sept. 5. On the evening of that day the reception will be held. The President of the United States, the Governor of Pennsylvania, the Mayor of the city of Philadelphia, Admiral Dewey, Gen. Miles, and a long list of distinguished statesmen and officers of the Army and Navy are to be present. The "Dog Watch" of Naval Veterans will be held Wednesday evening, Sept. 6, and on Thursday evening, Sept. 7, the National Association of Union ex-Prisoners of War will hold a camp-fire. Wednesday and Thursday, Sept. 6 and 7, will be given over to reunions of societies and business sessions of the National organizations. A great Naval Review, the grandest event of its kind, will take place on the Delaware River, Friday, Sept. 8.

Sight-seeing side-trips will be the order after the Encampment terminates. Many interesting places will be found near Philadelphia, where time may be pleasantly and profitably spent. Valley Forge, famous in the Revolutionary period of the Nation's history, is only a short distance from the city, and at League Island, another nearby point, may be seen the old-time and the new war vessels. Special rates will be made from Philadelphia to Gettysburg, Baltimore, Washington, and from Washington to the battle-fields of Virginia. Also to Old Point Comfort, Va. Daily excursions to Atlantic City and the famous seashore resorts along the Atlantic coast are run from Philadelphia over the Pennsylvania Double Lines to the Sea.

The great Pennsylvania route leads thru interesting

farming communities and pretty cities and towns in the Hoosier and Buckeye States. On nearing Pittsburgh it skirts the banks of the Ohio River before entering Union Station in the center of that city. From Pittsburgh the route passes scenes of industrial activity which have been likened unto the heart-throbs of America's manufacturing. Vast iron and coke interests spread out in pleasing panorama as the trains glide onward toward the romantic Allegheny Mountains. The tragic scenes of the flood-swept Conemaugh Valley have left their imprint in that historic vale. Traces of the memorable deluge are noticeable at and near the rebuilt city of Johnstown. At Cresson the Alleghenies are crost in the highest point above sea level. Horseshoe Curve, a marvel of mechanical engineering, is rounded on the eastern slope of the Alleghenies. The "Blue Juniata" River is followed through regions of enchanting grandeur. Just west of Harrisburg the Susquehanna River is crost on one of the longest and most substantial railroad bridges in the world. The country between that city and Philadelphia embraces some of the finest agricultural sections of America.

The best trains over the Pennsylvania Lines leave Chicago daily at 3:00 p.m. and at 11:30 p.m. Grand Army rates going are in effect Sept. 1, 2, 3 and 4. We expect to leave on the 3:00 p.m. train Monday, Sept. 4, which arrives in Philadelphia the evening of the next day at about 6:00 o'clock. We should be pleased to have any bee-keepers or others west of Chicago go with us on that train. If you desire it, we will be glad to make any advance arrangements for you that you may wish, so that you can be sure to make connections with the train that leaves Chicago at 3:00 p.m., Sept. 4, or on the one starting at 11:30 p.m.

REV. E. T. ABBOTT, of Missouri, expects to be at the Philadelphia convention.

MR. ELVERT W. HAAG, of Stark Co., Ohio, wrote us Aug. 5: "Bees did very well here this season."

MR. R. B. LEAHY, of the Leahy Mfg. Co., called on us last week, when on his way on a business trip thru Wisconsin. Mr. Leahy reports a most satisfactory season's bee-supply business. He looks as if he had been overworking in order to take care of the trade that came his way this year. But a man can stand a good deal of a strain for quite awhile if business is rolling in his direction.

MR. A. I. ROOT expects to spend a week or ten days in and around Boston, about the 15th to the 25th of this month. It is during the time of the meeting of the League of American Wheelmen in that city. It's just wonderful how that "60-years-old boy" gets all over this country. One time he is in Yellowstone Park, and the next time you hear from him he is in the city noted for its "larnin'" and baked beans! A *root* is generally supposed to be grounded pretty well, but this Root seems to thrive just as well, or better, when moving around on top of the ground or water.

MR. G. M. DOOLITTLE and his work are referred to as follows by "Stenog" in *Gleanings in Bee-Culture* for July 15:

"Writing to Mr. York, Mr. Doolittle says: 'I am fearfully driven with work now, and I have sore eyes, and a lame back to make work as uncomfortable as possible.' I have always felt it was a pity that Mr. Doolittle should spend his useful life in doing his own work instead of hiring help. If he had secured help during the last 20 years,

and had merely supervised his work, I am confident that a cipher would now be standing on the right side of every "S!" he can show. I do not see how any man can write as much for the press as he does without a stenographer, to say nothing of the great amount of work he does in his apiary and on his farm. I am speaking in general terms, of course, for perhaps Mr. D. knows his own business better than I do."

MR. G. W. BRODBECK is one of California's best known bee-keepers. In *Gleanings in Bee-Culture* for Aug. 1, J. H. Martin had this to say about Mr. Brodbeck and one of his dogs:

"Mr. Brodbeck and I have been sort of neighborly and sociable this season. He moved his bees into an adjoining canyon, within easy visiting distance, with some hopes of securing a little honey. But his hopes are blasted along with the rest of us, and I think they are a little blasted, for he is not only minus a honey-yield, but minus one of those bill-terrors. The poor dog fell into a reservoir and was drowned. It is supposed that the dog, being old and feeble, and his tail becoming so animated at the sight of water, it wagged the body into the reservoir."

PRES. E. WHITCOMB, of Saline Co., Nebr., in a letter dated Aug. 5, says he is going to the Exposition now in operation at Omaha, "in order to procure Indian dancers for the Philadelphia meeting." But we should think that unless Mr. Whitcomb has stiffened up a good deal in his joints the past year *he* could do all the Indian dancing that the program will call for at Philadelphia. Still, he may need the presence of a few Indian partners to help get up his enthusiasm.

Referring to local apiarian matters, Mr. Whitcomb says:

"The honey crop is very light, and with poor prospects for the future. During the early spring we had to hustle against foul brood, but found no case that did not succumb quickly to the starvation treatment, and have done pretty well since."

MR. E. W. BROWN, of Erie Co., N. Y., has been giving in *Gleanings in Bee-Culture* something of his experience with bees. In one issue he also told "how to put energy into a slow poke of a horse," which he used for peddling honey. Mr. Brown, being an electrical expert, and electricity being such a wonderful power these days, it is not surprising that he discovered a way in which to apply the current so as to sort of revivify a run-down horse. He explains it thus:

"The season last year was a poor one here as well as in most parts of the country; but with my 40 colonies, and 10 not mine, I produced three tons of honey, mostly comb, in plain sections, and increased to 60 full colonies and 5 weak ones. Of course, I had a fair fall flow. When I saw all this honey coming in I began to wonder how I could dispose of it. Dr. Miller says there are two things that bee-keepers are most interested in: 1. How to get a crop of honey; 2. How to get rid of it. I soon decided how I would get rid of my crop. I looked around till I found the best ten-dollar horse in the county. It had but a single fault—it wouldn't go. It would "whoa" better than any other horse I ever saw. After I bought the horse the former owner said that it was just a little inclined to be lazy. Perhaps electricity would be indicated in this case, I thought; and so one day I proceeded to attach concealed wires to the harness in such a way that I could, by pressing a button in the wagon, give the horse a mild electro-stimulus under its tail from a medical induction-coil run by dry batteries. This arrangement proved to be a great success, and it increased the value of the horse 175 percent. I can now overtake and pass anything on the road, to the great astonishment of the people who know the past record of the horse. One touch of the button furnishes sufficient ambition for a mile journey. I now seldom have occasion to touch the button, for the horse is nearly cured of its loss of ambition. When I speak it gives two switches of its tail, and away it goes. I have made good use of this horse in disposing of my crop; and as I now have an out-apiary four miles away, it will be a valuable help to me this coming season."

Mr. Brown should get a patent on his method of applying electricity in such a way as to overcome lost ambition in a horse. Wonder how it would affect a lazy man, if properly applied. Try it on—well, some other man besides Hasty, for if he is as quick as his name he doesn't need electricity around him.

Root's Column

HONEY WANTED.

We are in the market for both comb and extracted honey. If you have any to offer, let us hear from you **AT ONCE** stating the grade, number of pounds of each grade, from what source gathered and **HOW** it is put up. If extracted, send a sample by mail.

We Handle

Several Carloads Every Year....

and may be able to refer you to a buyer if we cannot handle it ourselves.

See our ad in this column for July 6th issue for

Honey-Packages...

Five-gallon square Cans are now \$7.00 per ten boxes instead of \$6.00.

THE A. I. ROOT CO.
MEDINA, OHIO.

In the multitude of counsellors there is safety. Prov. 11 14.

How to Get Rid of Ants.

Query 100. Do you know of anything that will destroy ants—something that will annihilate them entirely? ANON.

- W. G. Larrabee—No.
- J. A. Stone—Carbolic acid.
- D. W. Heise—I do not. Who does?
- Dr. C. C. Miller—Bisulphide of carbon.
- Prof. A. J. Cook—Yes; bisulphide of carbon.

Mrs. L. Harrison—Pour kerosene in their nests.

C. Davenport—No. Ants never injure bees here.

Eugene Secor—No, not that I care to recommend.

S. T. Pettit—Yes, I do. Give them lots of boiling water.

Mrs. A. J. Barber—We have had no experience with ants.

Emerson T. Abbott—No. Fire will reduce them to ashes.

J. M. Hambaugh—Coal-oil or carbolic acid, properly applied.

P. H. Elwood—Call on Dewey. They don't like salt very well.

O. O. Poppleton—No, except they are so situated that hot water can be used.

G. M. Doolittle—No. They do so little harm with me that I have ceased to fight them.

R. C. Aikin—Kerosene emulsion fixes every one you can hit, but I never get all of them.

R. L. Taylor—I think fire would be as near what you are seeking as anything mundane.

E. France—Put them into boiling water, every last one of them; or take a hatchet and chop their heads off.

J. E. Pond—I do not. Many plans are given in the bee-papers, but I have never had any serious trouble with ants.

Rev. M. Mahin—Fire will do it, but the application is not always easy. Salt and water will keep them away from the beehives.

E. Whitcomb—Find their nests and dose with kerosene. Rub lightly on top of the blanket and on the outside of the hive where they run.

J. A. Green—Bisulphide of carbon poured into holes made with a crowbar in the ant-hill, then covered with a flat stone or brick, has proven very effectual.

Mrs. J. M. Null—No. That is, that will destroy them but will not destroy the bees. Sugar and arsenic mixt together will be found equally effective in the destruction of both.

A. F. Brown—For practical and general use, no. Bisulphide of carbon, also kerosene, if poured in or over their nests will destroy them, but are too expensive; and,

27A1f Please mention the Bee Journal.

again, one cannot always find their homes. There is a large red ant that annoys beekeepers very much along this (Florida) coast. These ants will sometimes destroy a good colony of bees in a few nights, or even in a single night's attack.

C. H. Dibbern—Early in the spring when the ants appear on the surface is a good time to destroy them. Dig a hole into their nests, and pour in $\frac{1}{2}$ pint of gasoline—it will fix 'em.

Adrian Getaz—Yes, "Rough on Rats" mixt with honey will do the job. A wire-cloth should be placed so as to prevent the bees from reaching the "stuff." The ants can crawl in thru the meshes.

Dr. J. P. H. Brown—If their nests are under or near the hive use scalding water. Follow with a thick coat of quick-lime or tobacco-dust. If your hives have legs, or set on benches with legs or supports, paint around these with a solution of corrosive sublimate, and the ants will not pass over.

Dr. A. B. Mason—Yes, boiling hot water poured on their nests until completely saturated, or coal-oil. Where a quilt and a cover are used the ants will frequently do a "land office business" rearing ants between the quilt and cover. A little lime sprinkled where they congregate will effectually drive them away.

G. W. Demaree—O, my friend, you ask too much, unless you will permit me to suggest dynamite and blow up Old Earth. Practically, however, you can control the ants that infest your bee-hives, etc., by smearing wet salt in all their lurking-places. It is a little trouble, but it pays me largely for the extra labor.

E. S. Lovesy—I confess that I am stalled on this question. I have used cyanide of potassium, sulphur, salt-peter, vitriol, carbolic acid, strychnine, arsenic, London purple, Paris green, and many others, and I have destroyed many millions, yes, many bushels; but when we come to the scope of the question—a total annihilation of this pest—I have failed to accomplish the desired result. I have heard that there is a powder that will destroy them, which makes them crazy, so that they will kill each other, but so far I have not been able to find it. If any of our friends can solve this secret we will treat them like a prince, if they come our way.

Good Surplus Honey Crop.

We had severe winter losses here, but what we had left built up rapidly, and a good crop of surplus honey is now being taken off, principally from sweet clover, basswood and white clover. We have had fine rains, and the prospects for a fall honey crop are fine. The price of comb honey is 12 $\frac{1}{2}$ cents per pound.

KANKAKEE Co., Ill., Aug. 3.

Doing Moderately Well.

Bees are doing moderately well here. They stored some surplus from alfalfa bloom, but the webworm is fast destroying both bloom and leaf. The worms are also destroying katfir corn.

I have a good home market for all the honey I have produced so far. I am getting 15 cents a section for it. We have had the wettest July on record.

W. H. MEANS,

ada. Spring weather opened favorably, but unfortunately a large percentage of the bees had wintered poorly; however, during fruit and dandelion bloom they began to build up nicely. The clovers were pretty much all winter-killed, and what little survived failed to secrete very much nectar—barely enough to keep the bees alive.

Of course, our hopes for a harvest were built on basswood, which promised well, but it has come and gone, and we find most of our supers untouched. The atmospheric conditions have been peculiar, inasmuch as cool weather is concerned. While we have had abundant rains, yet not too much at any time; and while the days were sometimes very warm, yet the nights were always cool, and sometimes even cold. This low temperature at night, I think, is largely responsible for the light honey-flow.

But notwithstanding my light surplus of only six pounds on an average per colony, I am pleased to be able to say that the prospects are now good for the bees filling up their hives nicely for winter, for which we are very thankful indeed. I am also pleased to say that honey-dew has not made its appearance thus far. Swarming was very light so far as I have learned thruout the Province. D. W. HEISE.

Ontario, Canada, Aug. 5.

Bees Doing Well.

My bees are doing well. I saved two out of ten colonies last winter, and now have six, all working in supers. I have taken 72 pounds of honey from one colony, and will get two supers more from the same. Pretty good, isn't it? D. R. CRALL.

Du Page Co., Ill., Aug. 7.

Fairly Good Prospects for Honey.

The prospect for a honey crop hereabouts is fairly good, tho the bees did not begin work in the supers until nearly July. But tho the crop will be fair there will not be enough for home demand, on account of the greatly diminished number of colonies.

Bees have not swarmed much on account of the poor prospects in June, and when the harvest came it was so sudden that the bees lent their whole energy to the gathering of it. I have 10 colonies now, an increase of only two new swarms. This is what is left of 30 put into winter quarters last fall. S. H. HERRICK.

Winnebago Co., Ill., July 25.

Foul Brood—Careless Bee-Keepers.

Bees free of disease are doing well. White clover yields finely this year. Alfalfa is cut usually just as it is ready for the bees. Foul brood seems to be driving the bee-business out of the hands of the common farmers, as not one in ten will follow the inspector's instructions and clear their apiaries. An apiary that last year contained 80 colonies was reduced by foul brood to 29, and nearly all of these were

foul; all were shaken into clean hives and frames, and built up, equalized, and now we have 24 all on newly-built combs; these bid fair to store enough for winter.

We use a large solar wax-extractor 3x6 feet to melt the combs and honey out of the frames; even the candied and thick honey runs when the sun shines direct. (The brood and all foulness is cut out first.) The honey tho somewhat dark is quite good. The frames and slungum will be boiled later, and the wax taken out with hot water and a press.

We find few bee-keepers who will pay for bee-papers, and this discourages us in trying to educate them, but we are at home among the bees. A. T. FOSTER (Inspector.)
Boulder Co., Colo., July 28.

Rather Short White Honey Crop.

There is a rather short crop of white honey this year. It was largely caused by dry weather. I hope for a good crop from buckwheat and fall flowers. Many colonies were weak, owing to severe winter.

CHAS. B. ALLEN.

Oswego Co., N. Y., July 26.

Bees Have Done Nothing.

Bees have done nothing so far, even worse than last year at this time. I think in this part of the country we lost fully 75 percent of our bees, and if we do not get a good fall flow of honey, next winter will finish many more colonies. I fed my bees a good deal, a part of the summer.

D. J. BLOCHER.

Stephenson Co., Ill., July 28.

Bees Doing No Good.

Our bees are doing no good thus far this summer. We fed about \$12 worth of white sugar last spring, and have to feed again to keep the breath of life in some of the colonies, altho the first of June they were in the best of condition. All around us are many acres of red clover in full bloom; just across the road from our farm is a large field of 20 acres of red clover in blossom, but bees seem to get nothing from it. There seems to be some white clover, but the most of it was of this year's growth, and then the weather did not seem to be quite right while it was in blossom.

We have too many colonies in one place. I think, and we will unite and reduce the number as fast as we can. If put up at sale they bring but about \$1.50 to \$2.00 a colony, and I think it will pay best to unite all small and dark-colored colonies, and keep the combs for spring feeding, as we think they will get some honey yet this fall. We have now 140 colonies.

To care for bees at our out-apiary is very laborious, and we had to pay from \$10 to \$20 for the privilege of keeping them in a man's orchard, and if they failed to get a crop we felt it worse than when kept at home. I

don't know as they fail of a crop any oftener now that all are at home, than when kept in two apiaries. But when all are kept at home we don't feel the failure of a honey crop as we do when having them away from home, as we do not need to work with them much.

As we so often have a failure of the honey crop, it seems to me no one should engage in bee-keeping without some other industry to go along with it, except in favorable localities. A few colonies of bees may be profitably kept along with almost any other pursuit. It discourages people to keep them alone.

We are feeding now out-of-doors in a shallow box that holds about 3 pails of syrup, granulated sugar mixt with water, and the box has lath nailed together with little blocks between them to keep the bees from swamping in the syrup. They will take that amount up in less than an hour, and before I can get it all poured in they begin to come for it; in 5 minutes after poured in, the box or trough is covered

with bees, but they are very peaceable about it. I feed at all hours, or when it is convenient. Feed but once a day, about a tablespoonful to the hive. It is but a little bother to feed in that way.

MRS. L. C. AXTELL.

Warren Co., Ill., Aug. 2.

Getting Bees into Sections.

As I have read with interest the discussions of large and small hives, and the likes and dislikes for the shallow extracting-frame, I will tell you how I manage, mine with success.

I use the 8-frame dovetail hive, and the shallow frames, for starting the bees in the sections. I put the shallow frames on as soon as the bees get crowded; in a few days they will rush the honey up to make room below, then as soon as the flow comes I raise the super and place the sections under. When the sections are well started, extract the frames, and place them back in the super. Now raise the hive and place

the super underneath. This makes room for the queen. By cutting out queen-cells once I kept down swarming this season, and my best colony gave me 60 pounds of clover honey. My colonies are very strong in bees.

I think a good deal of the "Old Reliable."

A. A. WENNEKER.

Montgomery Co., Mo., Aug. 7.

Not a Very Good Season.

I have 80 colonies of bees at present, and am getting two shipments per week from Wisconsin. The season here so far has not been very good, as we have had too much rain, but the prospects are good for a fall flow from asters, fireweed and Spanish-needle.

I can't get along without the "Old Reliable"

E. C. NOLAN.

Midland Co., Mich., July 31.

Not a Good Season.

The season has not been a good one for bees in this locality. The spring was late, and there was too much rain in May and June. Conditions are improving. I bought one swarm in the spring of 1898, captured another, and bought two more this spring, and I now have 14 colonies, all doing well, and some of them busy in the sections.

CHAS. W. WOLBERT.

Union Co., S. Dak., Aug. 1.

Fair White Honey Crop.

Bees are gathering but little honey now, tho if we had a rain they would make a living until buckwheat bloom.

The crop from white clover was fair both in quality and quantity. Sweet clover is still in bloom, but bees work on it but little except in early mornings.

H. G. QUINN.

Erie Co., Ohio, Aug. 2.

Bees Have Done Poorly.

This part of the country was visited by a terrific hail and wind storm July 6, which took my entire farm crops. My bees have done very poorly; there was no basswood honey, still the trees bloomed profusely. I have six colonies of hybrid and black bees. I intend to get six Italian queens this fall and Italianize my bees, which I transferred from the woods.

C. A. WARNER.

Kandiyobi Co., Minn., Aug. 2.

Not Doing as Well as Last Year.

Bees are gradually filling their supers, but are not doing as well as last year. Here the honey never comes in fast—between 3 and 4 pounds a day is the best I have noticed on the scales under my best colony; but our season is a long one, and I have never failed to get a surplus ranging from 30 to 200 pounds per colony.

Hall Co., Nebr., July 29. J. F. EGGERS.

The Novelty Pocket-Knife

A heavier and stronger knife than the one we offered heretofore.)

THIS CUT IS THE FULL SIZE OF THE KNIFE.)

Your Name on the Knife. When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the Subscriber.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the Novelty is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the Novelties, your Pocket-Knife will serve as an identifier; and in case of death, your relatives will at once be apprised of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife. We send it post-paid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal, with \$3.00, and we will also send to each new name a copy of the Premium Edition of the book, BEES AND HONEY. We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Aug. 9. At this date very little comb honey has come on the market of this season's yield, and none of it would grade more than No. 1; it has sold at 12 1/2 cents, not any dark or amber offered. Extracted sells readily at 7 1/2 c for white; amber, 6 1/2 to 7 1/2 c; dark, 6 1/2 c. Beeswax, 25 1/2 c. R. A. BURNETT & Co.

KANSAS CITY, July 7.—A small shipment of new comb honey on the market is selling at 14 1/2 c. Good demand. C. C. CLEMONS & Co.

NEW YORK, Aug. 9.—Old stock is entirely cleaned up, and good demand now for new crop. We quote: Fancy white, 13c; No. 1, 12c; fancy amber, 11c; No. 1, 10c. Extracted in good demand with market firm. Fancy Florida, 7 1/2 c; choice, 6 1/2 to 7c; amber, 5 1/2 to 6c. Other Southern, 6 1/2 to 7c per gallon for choice, and 5 1/2 to 6c for common. No demand for buckwheat honey at this time. Beeswax dull at 25 1/2 c. HILDRETH & SEIGELKEN.

SAN FRANCISCO, Aug. 2.—White comb, 11 1/2 to 12 1/2 c; amber, 8 1/2 to 10c. Extracted, white, 7 1/2 to 7 3/4 c. Light amber, 6 1/2 to 7c. Beeswax, 26 1/2 to 27c.

A shipment of 12 cases extracted went forward by Panama steamer this week for New York. Market is decidedly firm for both comb and extracted, especially for best qualities. Stocks are small, both here and in the interior.

CLEVELAND, July 22.—Fancy white, 13 1/2 to 14c; No. 1 white, 12 1/2 to 13c; A No. 1 amber, 10 1/2 to 11c; No. 2 amber, 9 1/2 to 10c; buckwheat, 8c. Extracted, white, 7c; amber, 6c; buckwheat, 5c. A. B. WILLIAMS & Co.

BOSTON, May 17.—Fancy white, 12 1/2 to 13c; A No. 1, 11 1/2 to 12c; No. 1, 10c; light amber, 9c; buckwheat, 8c. Extracted Florida, white, 7 1/2 to 8c; light amber, 6 1/2 to 7c. Beeswax, 27 1/2 to 28c.

The demand for both comb and extracted honey has settled down to the usual small proportions of summer, and prices quoted would be shaded some, too, as stocks are a little heavier than is liked at this season of the year.

BLAKE, SCOTT & LEE.

BUFFALO, Aug. 4.—The honey season has opened in a moderate way, a few small lots of new arriving. Extra fancy 1-pound combs, 13 1/2 to 14c; fair to good, 11 1/2 to 12c; dark, poor, etc., 8 1/2 to 9c. BATTERSON & Co.

OMAHA, July 18. Although first receipts of new crop Southern honey were recorded early in June, there has not been any regularity about them since. A straggling lot of comb turns up now and then, and when quality is choice to fancy, is eagerly picked up at 14 1/2 to 15c. A little lot of 1898 crop was received a few days ago and went at 13 cents, quality not above choice. For extracted there is not such an urgent demand, still, 7 1/2 to 8c would be obtainable in a small way. The heavy buyers will hold back until later in the season, expecting to purchase on about the same basis of value as last year. Early shipments of all the comb that can be gotten out is certainly advisable; there will not be any chance of holding out with present quotations after the first demand is satisfied. PEVECK BROS.

DETROIT, July 15. No old honey to quote, and no new offered. Prices are liable to rule higher as crop is short. The abundance of rain will no doubt help the crop of fall honey. Beeswax in good supply at 23 1/2 to 24c. M. H. HUNT & SON.

WANTED. Comb and extracted honey; state price, kind, and quantity.

CONTRIBUTED ARTICLES

Wintering Bees in the Cellar.

BY C. DAVENPORT.

LAST winter I had a number of colonies starve to death in the cellar, and many others were nearly or entirely destitute of honey when the hives were put out. One colony in particular was, it appears, in the last stage of starvation. It was medium strong, but the bees were so weak that when the hive was put on its stand they made no effort to fly. On examination, I found there was not a drop of honey in the combs. When handling the frames on which the bees were clustered, they would merely raise and flutter their wings a little.

In fact they appeared and acted just like bees do when they are chilled. I put three or four frames of sealed honey in the hive, then sprinkled warm, thin sugar syrup over the bees, and in a short time they were lively, and appeared to be none the worse because the wolf of starvation had entered their door, and from appearances staid with them for some time.

Such a case had never before come under my observation. I supposed that when a colony starved to death they did so gradually, a few at a time, but in this case, at least, it appears they took means to distribute their stores and shared alike while they lasted, and all would have succumbed at once or within a very short time of each other.

When the hives were put into the cellar I thought that each colony had plenty of stores to last them until they were put out in the spring, and for some time after as all eight-frame hives weighed 50 pounds or more. I had taken special pains in the fall to feed, or furnish sealed combs, to colonies in light hives, but there was an excessive amount of very heavy pollen in nearly all the hives. We had a great drouth here last fall, and brood-rearing stopt earlier than I ever knew it to do before. It was probably on this account that there was so much more pollen in the combs

than usual, for I did not notice, and do not think, that there was more gathered last season than there commonly is. Most, or a great deal, of it was in the bottom of the cells with honey on top, or I undoubtedly should have noticed in the case of many colonies that they were short of honey, and in looking back it appears very strange to me that I did not think about the matter, anyway; but my experience and loss may be the means of saving a loss to others under similar circumstances.

For the benefit of those without much experience, who winter their bees in the cellar, I am going to say a few words, and on account of the great severity of last winter, probably many will put bees into cellars next winter, who have been wintering them on the summer stands.

In my immediate vicinity not a single colony that was left out-doors last winter survived, but most of the bees around here that were wintered out-doors were kept by farmers, who, when they protected them at all, mostly did so by throwing straw or cornstalks over and around the hives; but it hardly seems possible to me that bees could have lived thru last winter out-doors, even if protected by the most approved method of packing, for aside from the extreme and long-continued cold-spells, there was not, from about the middle of November until the forepart of April, a really suitable day for them to fly.

The time to put bees into the cellar depends, of course, upon the locality. For the last few years I have left mine out until the latter part of November, but last fall about the 20th of that month there was a severe storm, with extreme cold; I think I lost, at

Apiary of Jacob Hoffman. See page 522.

a low estimate, \$100, because my bees were out in it, and after this the majority of mine at least will be put under ground by the middle of November.

Some recommend placing long scantling, or 2x4, in the cellar to set the hives on. I used to practice this plan, but I have found that a much better way is to put an empty hive or stout box under each tier of hives. When this is done, only the colonies in that one tier are disturbed when a hive is put on or taken off. When long pieces are used, unless great care is taken, the bees in all the hives on them are more or less disturbed when a hive is set on, or removed in the spring.

For the past two winters I have left the bottom-boards on, and for reasons I will not here take space to explain, I consider it better to leave them on and raise the body of the

hive up so as to leave an open space all around under it. Before commencing to carry the hives in, I set empty hives about a foot apart in rows thru the cellar, and level them up sidewise, but raise one end so that it is about an inch higher than the other. I use a spirit-level for leveling these stands, for it is an important matter to have them about level, if the hives are to be tiered six or seven high, as mine are; for if they are not they may lean over so far that in a cellar that has no floor but the ground, one tier may topple over, and its fall throw other tiers over, like a set of nine-pins.

For carrying the hives from the yard to the cellar, I use a carrier that is made so that two hives, or even three, if they are not too heavy, can be carried at once by means of handles similar to those of a wheel-barrow, that project out at each end. It requires two men to carry them in this way, but if the hives are some distance from the cellar it is, I think, much better to use something of this kind instead of a wheel-barrow, as with a carrier the bees hardly seem to know that they are being moved.

On a cloudy day, with the temperature at 40 degrees or lower, I seldom find it necessary to close a hive-entrance. After a hive has been put on its stand in the cellar, I raise it from the bottom-board, which has been loosened a day or so before; a short piece about one-half an inch thick is put under at each corner, and from some pretty extensive experiments I have made in this line, I am convinced that a colony will winter fully as well with the hive raised half an inch from the bottom-board all around as it will if it is raised an inch, or as it will with the bottom-board left off entirely; in fact, many of my hives that have strips on the bottom-boards I only raise the thickness of a lath all around, and have decided that with me it is better than to have them raised higher. I try, tho, to keep the air in the cellar pure, and the rows of hives are far enough apart so that one can walk between them and remove the dead bees on the bottom-boards, if they accumulate so as to make it necessary.

I consider it better to give ventilation enough to keep the air pure, even if doing so does, to some extent, cause an uneven temperature. A few colonies in a cellar of considerable size will, in most cases, obtain plenty of air without any special means being taken to give ventilation, but in a cellar that is well filled up with bees, some means should be taken to admit fresh air at will.

Of the numerous methods I have tried for giving ventilation, I prefer a pipe or tube running from the cellar up thru the roof, independent of any other pipe or chimney, with a suitable hood over the top to prevent rain or snow from running down, and with a damper on the same principle as a damper in a stove-pipe, where it can be most easily reacht, so that it can be regulated as the weather demands.

Southern Minnesota.

A Switzerland Blind Bee-Keeper.

BY D. GRANT.

IN the Revue Internationale D'Apiculture is a long and most interesting description of an apiary in Switzerland, with photos of it and its surroundings. It is remarkable for two reasons, first that it is over 3,000 feet above sea-level, only a few hundred feet below the line of perpetual snow, and within 1 1/2 miles of one of the large Alpine glaciers with a winter temperature of 50 to 60 degrees below freezing, and snow on the ground for eight months of the year; and second, because the owner and manager is not only a cripple, but *absolutely blind*.

This bee-master (for such on further acquaintance he proves himself to be) has about 30 hives arranged in two tiers on the south side of a large shed. The other three sides are closed, and a door at each end leads into the back part of the shed, where spare hives and combs are stored, and where the operator stands to manipulate his bees. In winter the spaces between and around the hives are filled with dry moss, and large shutters close the open part of the shed.

He keeps a first-cross Carniolan-German bee, and has found that the first are very given to swarming, while the cross is nearly a non-swarmmer. Italians he has found too vicious, and not well able to stand the severe winters. He uses a hive containing seven frames about 11 inches square comb measurement for the brood-nest, and shallower frames in the extracting-supers, of which he has as many as four on some hives in the photo. He knows when to expect a swarm by the different noises in the hive, and the piping of the queens. An old straw-skep inverted on a stake a few

yards in front of the apiary forms a never-failing swarm-catcher. He is, however, but little troubled with swarms, having only had three last year from 25 colonies.

To distinguish the brood from the honey he touches the surface of the comb with a chip of wood, and can tell by the difference in the feel of the cappings how far the brood extends.

His plan for uniting colonies, judging the strength of a colony, introducing queens, etc., are all unique in their way, while his dodge for finding and killing an old or condemned queen is too good to pass over. He moves the hive, putting in its place the hive he wishes the bees to go to. This may contain a caged queen (for requeening) or a weak colony (as in uniting). He then draws out the back frame of the old hive, shaking the bees off, and places it in the new hive. Then he drops into its place a frame full of syrup in the combs. In a few minutes this is covered with bees. This he shakes into the new hive. He then takes out the next comb, shaking off all the bees. This also goes into the new hive. In a few minutes he drops his frame of syrup in, leaves it awhile, and when covered with bees shakes them into the new hive. He does this until he gets to the last frame. This one, he says, always has the queen on it, and he plunges it, bees, queen and all into hot water. The bees shaken into the new hive, being gorged with syrup, are always accepted without trouble.

This bee-keeper has neither veil, smoker nor brush, and uses his hands to remove the bees from the combs. He says, quite contentedly, that his bees know him, and would not sting him because he is blind. He has never heard anything read about bees, nearly all he says and does is from his own observations. He does everything in connection with his bees himself except foundation-making, at which his father helps him and extracting, his father's share of this work being the uncapping.—Australian Bee-Bulletin.

How I Started in Bee-Keeping.

BY J. F. SAUTTER.

IN July, 1897, father sent three of us boys to a neighbor's to pick cherries. The day was warm and bright. About three o'clock in the afternoon, while we were in the trees picking, we heard a strange sound or humming, and on looking out of the foliage we saw a swarm of bees flying up the ravine toward us. I do not think there were ever three boys that got down from the top of a cherry-tree quicker than we did.

Just as soon as we were on the ground, I gave the order to throw sand and gravel in the swarm, which was done with a will. The air was full of sand and gravel for a minute or two, when the swarm stopt and began to cluster on an elder-bush. Then a shout went up that would have surprised an Indian.

Now, what were we going to do with them? The nearest bee-keeper lived about one mile away, and after some arguing one of us volunteered to go after a hive, or see if we could get one. Luckily, the good neighbor had just one hive on hand yet—a box-hive, which he sold to us for 25 cents.

The next thing was to hive the bees. None of us were very brave with them yet, altho we had had plenty of fights with bumble-bees on our farm, and ruined many a straw-hat in the excitement. But these bees we did not understand so well. We had heard father tell how he hived a swarm for a neighbor once, so we started.

The swarm being clustered on an elder-bush, we were at a loss to know how to get them off; but this is the way we did it:

We set the box-hive up just about as close as we thought we were safe, then taking out our pocket-knives we whittled the elders off, and gently laid them down in front of the hive, when, to our delight, the bees began to march into the hive.

Now we had another question to argue—How were we to get them home? We had with us a strap long enough to tie around the hive, and by taking it and a pole we swung the hive between two of us boys, after closing the entrance with grass. Getting our strap and pole on, we started for home. We felt about as good as Joshua and Caleb must have felt when they were coming out of Canaan, only they had grapes, and we had bees and cherries.

Just as we appeared in the yard at home, father came in from the barn. I can yet see the puzzled look on his face. He did not know whether to scold or not for bringing the bees. He did not scold, tho, but told us where we might

set them, and after getting them on a stand, and the grass out of the entrance, we explained how we got them, altho we had some trouble in doing it, as we all wanted to talk at once.

After supper we talk bees. It would have made a bee-keeper smile to hear us. It lasted until bedtime, and after we were in bed I discovered that I had caught the bee-fever, as I could not sleep, the bees being so much on my mind.

My two brothers did not take the fever, so I bought out their interests the next day, and then started to get more information on bee-keeping. I searched the house for the back numbers of a farm journal which contained articles on bee-keeping. The first one I found was written by Dr. C. C. Miller, and then other articles by George Spittler. If every farmer would read the articles in the farm journals as I did, I am certain there would be more farmer bee-keepers that would make bees more of a success.

As my first swarm was cast in July, it did not have much honey for winter. I did not find anything in the farm papers about wintering or feeding for winter, so I askt the neighbor bee-keeper how to feed. He told me to make a syrup of sugar, and drop it down among the bees on the cluster, which I did when the days were warm enough for them to fly. They lived until the next spring, then cast a swarm, and gave some surplus honey.

In the winter I saw the advertisement of the American Bee Journal, sent for a sample copy, and mailed my subscription the next day after receiving it. I also got "A B C of Bee-Culture" and other books on bees, and all the while the bee-fever is getting more hopeless, as my study and experience advance.

Stark Co., Ohio.

Secrets of Selling Honey in the Home Market.

BY H. D. BURRELL.

HOW to dispose of the honey crop profitably is becoming a serious problem with most bee-keepers. Not many years ago it was easy to produce comb honey, ship it to some commission house in a near-by city, and realize 16 to 20 cents a pound for it. Now in many places most of the honey-producing timber is gone, and waste lands reclaimed and cultivated. These causes, with frequent poor seasons, render the honey crop uncertain; and, worst of all, comb honey in the cities is quoted low.

Formerly I produced comb honey almost exclusively, and shipped nearly all of it to commission houses. But some years ago I unexpectedly had about a ton of autumn extracted honey to dispose of. Shipt to a commission house it would probably have netted 4 to 5 cents a pound, *some time*. I had never tried peddling honey, and was very much prejudiced against peddlers and peddling; but I wanted more for that honey. I loaded some of it into the wagon, put up in convenient packages for retailing, and started, tho with much trepidation. I knew a few rebuffs would send that honey to the city for what it would bring. But I sold honey at nearly every house, over 300 pounds the first day, and decided that peddling (honey at least) was not such bad business, after all. Many neighbors and acquaintances who had past by frequently for years and seen the sign, "Honey for Sale," but never bought a pound of my honey, bought freely when it was carried to them. And they didn't buy afterward, either, unless I carried it to them and askt them to buy.

The ton of honey was soon sold at 8 to 11 cents per pound, according to quantity wanted, and several thousand pounds more were bought and sold at a fair profit. Since that time I have produced mostly extracted honey, always retail it myself, and am getting the same prices now in these times of very low prices that I did ten years ago. Honey, if a good article, will sell itself almost anywhere, if given a fair chance. I have never found a place, in country or town, where it would not sell fairly well at any time of year, tho in the fall is the best time to sell, in my experience, after the bulk of fruit is gone, and the many needs of the winter season have not yet taxt the pocket-book.

But I think I hear some one say, "I can't peddle," or "I won't stoop to peddling." Now, neighbor, stop a minute, and listen. When I was young and green I tried "canvassing" for a book. For years after, I had a horror of peddling. When I came to keep bees, and have honey to sell, I would not even ask a merchant with whom I traded regularly, to buy my honey. If any one but a commission man wanted any of it, he had to ask for it. I am not a natural salesman, a poor talker—timid, diffident, and easily rebufft. I can, however, sell an average of 100 pounds of honey a day in any fairly good farming country, and in

villages and towns often much more. You will find selling your own honey different from selling books or notions. People will be glad to see you come. You need not lose one atom of your dignity, if it is of the self-respecting kind. If any one thinks any less of you for selling honey, providing you are polite and respectful, it will be some one whose opinion is not worth minding. Any one with a little tact and energy can dispose of 3,000 to 5,000 pounds of good extracted honey at fair prices, at odd times in fall and winter, when time is not worth much, and much more can be sold by devoting more time to it.

Comb honey is not satisfactorily retailed, in my experience. It too easily gets to leaking, and is then mussy and not attractive. Sell comb honey only by the case, if at all. Perhaps I may be pardoned for saying, in such an article as this, that I have for many years kept from 50 to 195 colonies of bees, and have produced and sold over 60,000 pounds of honey, and bought and sold much besides. I write facts learned in the dear but thoro school of experience, and not plausible theories.

First, secure a good article of well-ripened extracted honey, and so care for it that it will remain good. My ways of doing this differ from the usual ones; but I will not take time now to explain.

When we are ready to sell, if the weather is mild, attach a sliding faucet to a five-gallon screw-cap tin can of honey; place the can on the wagon-seat, the dish to be filled on platform scales underneath, and weigh out any quantity wanted. It is usually most satisfactory at this time of year to let the purchaser furnish the dish, then there is no package to pay for or return.

Some writers have advocated selling not less than one dollar's worth when selling honey direct to consumers. I can't agree with them. A small sale often paves the way to a large one later, and it always pays to be accommodating and obliging; but I charge one cent per pound more for less than a dollar's worth.

In cold weather, when honey will not run readily, I put up honey in one, two, and four quart tin pails, and charge extra for the pails. Always, to every package sold, attach a neatly-printed label, giving your name and address, and plain, simple directions for so caring for the honey, that it may retain its good qualities until used. Dress neatly but plainly, like a farmer, not like a city man. Have everything neat, clean, and attractive.

Now we are ready, how shall we find buyers? Fill a small new tin-pail with honey, and label it. Call at every house—skip none. You will often make sales where you least expect it. When the door is opened say, "I have some choice honey, please get a spoon and sample it." Right here is the main point. Get every one, if possible, to taste your honey. Most people have sweet teeth, and a taste of good honey puts them in good humor. Be very sure that the children, if present, have a taste, too. If you don't know already that parents' hearts are very easily reacht thru their children, you will soon learn it. If a servant or child goes to consult the housekeeper about buying honey, see that the honey-pail and spoon go, too. Twenty-four people out of 25 would say, "No!" if askt if they wanted to buy extracted honey. If they taste first, many will buy. Many are prejudiced against extracted honey. Perhaps some time they have had a poor article of extracted or strained honey, or, may be, they think the honey is bogus. I have many times had such people taste my honey and say in a surprised way, "Why, that is good. That is genuine honey. What is the price?"

One lady said to me last fall, "I never buy extracted honey. I buy comb, then I know what I am getting." After she had been induced to sample the honey she found it good, knew it was genuine, bought some, and askt me to call again.

Don't annoy people by urging them to buy when they don't want to, and be invariably polite and pleasant whether they buy or not. You can easily make friends who will be glad to see you come again. Follow the same route every year, and your sales will increase each trip. You can go over the same ground as often as once in six weeks to advantage. I have many customers who at first bought lightly, or not at all, who now buy 20 to 50 pounds of my honey every season. One near-by town of about 2,000 population has used over 1,500 pounds of my honey up to Feb. 1, and all autumn honey, too. I seldom have any other kind in my present location. But there is little backwheat, and the honey is mostly from golden-rod, fireweed, and Spanish-needle. One pleased customer will often find others for you. In this way in one season I sent three 5-gallon cans of honey to customers in Chicago, at 9 cents per

pound net. "Can't buy genuine honey in Chicago?" they say. A little ridiculous, isn't it?

Some one will ask if I have no competition in selling honey. Yes, but that doesn't matter much. There is plenty of room, and customers for all. Make a reputation for square dealing and selling a good article, and customers will wait for you. If some one undersells you, and gets some of your customers, never mind there is a very large market almost entirely undeveloped.

Think of this matter, brother bee-keepers. Plan to produce a crop of good extracted honey next season, and then get all there is in it. Don't divide with transportation companies or middlemen. A crop of extracted honey is much surer than a crop of comb, and, in most localities, two or three times as great. Ask a fair price for your honey (all you can get is a fair price), and adhere to it. It is much easier to lower prices in a good year than to raise them in a poor one. If there is a large or small crop of grain or fruit, every one knows it. Not so with honey. Gleanings in Bee-Culture. Van Buren Co., Mich.

Poor Apiarian Conditions in a Vermont County.

BY G. W. FASSETT.

EDITOR YORK: I send you a clipping from our local paper for Aug. 4, which reads as follows:

NO HONEY THIS SEASON.

The long drought in June had an indirect result on our Addison county industry not noted at the time. Honey-producing, G. W. Fassett, of this place, who owns 100 colonies of bees, informs us that he will secure only about 500 pounds of honey this year. He notes the fact that L. O. Thompson, who last year secured 13 tons, will have none this season, and J. E. Crane, who marketed 14 tons in 1898, will get about 500 pounds this year. The two latter gentlemen will have to feed their bees until next spring, and this will require about eight tons of sugar each. This season has been the worst Mr. Fassett has ever known, and he has been a bee-keeper since his youth. The five largest bee-keepers in Addison County are J. E. Crane, L. O. Thompson, V. V. Blackner, R. H. Holmes, and W. G. Larrabee. Together they own about 2,000 colonies of bees, or one-third of all owned in the county. Last season over 100 tons of honey were shipped out of Addison County; this year there is not enough for home demand. In some parts of the county owners for several weeks have been feeding their bees to keep them from starving. Reports of actual starvation have been received. It is a notable fact that the worst season for maple sugar Vermont has experienced in many years should be coincident with a like failure in honey-producing.

In addition to the above I would say that our county is small, and contains quite a variety of soil and climate for so small a territory. The western part lies on Lake Champlain, and extends east over the range of Green Mountains. The loss in bees last winter in the mountain towns was over 50 percent, and in the towns not over 10 or 15 percent. The early spring promise fair; bees filled their hives with both honey and brood; clover looked as fine as I ever saw, but it came on dry, and the clover did not yield honey enough to keep the bees from starving; only a few bee-keepers put on any sections. One of the largest bee-keepers said he put on a few supers to see if the bees would draw out the foundation. He said they did, *i. e.*, they drew most of it out of the sections.

When the clover failed then all the bee-folks look forward to the basswood bloom for their surplus honey. We get very little tall honey. Basswood blossomed full, all the little trees were full of blossoms, and I am at a loss to know what kind of weather it needs to make basswood yield nectar. We have a long spell of basswood bloom from the lowland to the height of the mountains where the basswood grows, and we had all kinds of weather. There came plenty of rain, but no honey; then cool weather followed by more hot and dry weather, but no honey in the basswood, which means a good many dead colonies before next spring. And not only that, but there will be a good many tons of sugar fed to keep bees from starving.

It has been a hard season for those that make a practice of requeening their bees; they have had to feed to get the

Jacob Huffman's Barn, full with one season's Honey Proceeds.

bees to build queen-cells, and have also had to feed to get the bees to rear drones.

BEES STARVED FOR WANT OF POLLEN.

I see on page 450, Prof. Cook speaks of some finding dead brood in hives with plenty of stores. We find it in hives with plenty of honey, but fail to find pollen in the hive, and I think it is starved brood, the same as when there is no honey. Addison Co., Vt., Aug. 8.

Mr. Jacob Huffman and Apiary.

Wisconsin is one of the great honey-producing States of our country. A few weeks ago we gave a picture of Miss Pickard's apiary, and this week another. Mr. Huffman has this to say about it and his work with the bees:

The view of the bee-yard shown here was taken without any preparation whatever, shortly after taking the bees from their winter quarters. I would have been glad if the view could have been taken a month later in the season, if to be placed in the American Bee Journal.

I have been in the bee-business about 23 years, beginning upon a small scale, and I consider myself as yet an amateur. I have had successes and also some small failures. There have been years that I have realized more clear profit from my bees than off the farm. Those who have followed bee-keeping understand that we have occasionally dry seasons, and sometimes those too wet to realize a profit. Only one season in my experience was feeding for winter found necessary.

The illustration of the barn will give an idea of my profit for the year 1885.

In my immediate locality the honey season is much shorter than it was a few years ago. Basswood, which is one of the best honey-producers, has been cut off, as the timber is being cleared away, and farms are everywhere instead. It has become necessary for bee-keepers to be ready for the honey season if they expect any surplus as a recompense for their labor. The prospect for this year is not so flattering, but considering the hard winter we past thru, I am very thankful for present prospects.

Green Co., Wis.

JACOB HUFFMAN.

In further explanation we might add that the year Mr. Huffman's honey crop paid for his nice barn, 36x40 feet, he had 140 colonies, which produced 14,000 pounds of extracted and 6,000 pounds of comb honey, which sold for \$1,280.

In the first picture Mr. Huffman is shown operating a McCartney section-press and foundation-fastener. The building at the left is an old house used as a shop, and the one near the left is an extracting-house located in the center of the apiary.

We had the pleasure of meeting Mr. Huffman at an

annual convention of the Wisconsin State Bee-Keepers' Association held in Madison several years ago. He undoubtedly is a bee-keeper who thoroly understands the business, and a splendid talker at a convention.

Dr. Lortet's Paper on Foul Brood.

WE have much pleasure in giving our readers a translation from the *Revue Internationale* of a paper by Dr. Lortet, who has for some time been making experiments and observations upon this disease. There are many points quite new, and which throw considerable light upon the subject, and the remedy proposed is simple, and, from reports, encouragingly effectual. We wish our readers to particularly note that the naphthol is that known as naphthol beta, and not the ordinary naphthaline. As it is perfectly harmless, there is no danger in its application:

"Thanks to the publicity you were good enough to accord me in the columns of *La Revue*, I have received from a number of your readers pieces of foul brood comb, or bees exhibiting more or less advanced stages of the disease. I have, therefore, during the last year been abundantly supplied with material for my researches, and have been enabled to clear up a good many obscure points in connection with their virulent affection, and to formulate a course of treatment based on careful laboratory experiments.

"As was demonstrated in the contributions by Mr. Cheshire (*Revue*, August, 1884) and Dr. Klamann (*Revue*, January, 1889), foul brood is in reality produced by rod-shaped bacteria which develop rapidly in the brood-cells and soon die, and produce in putrefying an odor which is altogether unmistakable.

"Before beginning my observation of foul-brood larvae, either during the disease or after death, and of adult insects already infected, I turned my attention to perfectly healthy bees, as well as various other species of hymenoptera, such as wasps, humble-bees, carpenter-bees, etc. After a patient and minute course of dissection I have arrived at the following results, which are based on an intimate acquaintance with the aetiology of the disease:

"I. I find that various hymenoptera, besides adult bees, whether healthy or diseased, *invariably present*, thru the whole of the lower part of the digestive tube, a very large number of bacilliform bacteria, which are probably called upon to perform important, tho at present unknown, functions in connection with the chemical changes which take place in the food introduced into the digestive canal.

"In the bee, to mention only the species which immediately interest us, whether healthy or diseased, as well as in the digestive canal of the brood, whether in health, in disease, or after death, I have invariably discovered two normal bacilli, the presence of which has, without doubt, led some people astray.

"The more numerous of these bacteria are of a large rod-like shape, broad, thick, short, and bear a striking resemblance to certain bacteria which are frequently met with in soft water. They are never arranged in chains, but propagate themselves by means of binary fission; in the early stages they are often united in couples. When fully developed they become slightly rounded at the extremities, which swell perceptibly. These bacteria retain very well the stain communicated by Fuchsin, and after staining the club-shaped ends show a much darker tint than the central space of the body. In this state the bacteria present the same appearance as may be observed in the bacteria of malignant oedema.

"This species is most easily cultivated, especially in liquid media, less easily in nutrient Agar-Agar glycerine gelatine. When injected into the cellular tissue of guinea-pigs it fails to produce any harmful effect.

"II. Another normal bacterium is also invariably found in the digestive canal of the bee. It is smaller, thinner, and short, its length being only equal to twice its breadth; it is not rounded at the extremities, which are shaped almost at right angles. These bacilli do not form chains, but frequently remain united in pairs for a long time. In this state they nearly resemble diplococci, tho perceptibly more elongated than these latter. In cultivation they often group themselves into *coagula*, and in this case arrange themselves very regularly. These microbes multiply without difficulty in both solid and liquid media, and take a strong stain from Fuchsin, or Methyl, or Gentian violets.

"III. Lastly, in the digestive canal of dead or diseased

brood, as well as of adult bees already infected with the disease, but in the digestive canal alone, a third kind of bacterium is found, which is without doubt one of the forms that have been examined by Mr. Cheshire. It is thin, and frequently extends in filaments. It thrives well in sterilized veal-broth, and it is therefore comparatively easy to obtain a supply of perfectly pure specimens for purposes of inoculation. In this nutritive element filaments appear in a few days, and after staining the fine granular elements of the formation become apparent owing to the differences in coloration.

"In the digestive canal of the adult the bacteria appear to maintain their rod-like shape for a considerable period perhaps, indeed, always; whereas in the digestive canal of the larvae, probably owing to the influence of albumenoids, which pass by osmosis thru the walls of this tube, the bacteria, as in the case of cultivations effected in unsalted veal-broth, are rapidly transformed into very fine, virulent granulations, which invade all the tissues, and soon bring about the disorganization and rapid putrefaction of the larvae.

"The adult bee, on the other hand, even when the foul-brood bacteria have taken possession of its digestive canal, seems to be able to live for a certain time. It is, however, none the less apparent, once the infection has taken firm hold, that the animal is diseased. The digestive canal, and especially the surrounding glands, end by being invaded by an enormous number of the rod-shaped organisms; the insect loses its vivacity, grows languid, and finally perishes after a more or less protracted interval.

"Virulent granulations cultivated in salt veal-broth, or on plates of glycerated Agar-Agar, produce bacillary bacteria, which, when given in food to the larvae, undergo in their turn segmentation into virulent granulations, whereas in the case of the adult bees, they still probably retain the bacillar form for a long time, tho they do not fail in the end to cause its death.

"The culture and transformations of the foul-brood bacterium cannot take place in the honey; so much is certain. Still, I may mention that in diseased hives the honey and wax are always more or less infected on the surface by bacilli, virulent granulations, excrements, etc.

"I have on several occasions succeeded in reproducing the whole series of phenomena mentioned above experimentally, and have, without difficulty, infected insects which had been perfectly healthy and vigorous up to the moment of the experiment. My mind is, therefore, quite free from doubt in the matter. It is the adult bee which is first infected in its digestive canal by a foul-brood bacterium obtained from some unknown source. In feeding the larva it infects in its turn the digestive tube of this latter, and here, owing to the action of the albumenoids, the bacillar bacteria are transformed into virulent granulations, which invade the tissues and finally bring about the death of the insect.

"Contaminated honey may be a cause of the propagation of foul brood in the sense that, being polluted by foul-brood bacteria or by virulent granulations, the healthy adult bee which allows this substance to enter its digestive canal is rapidly attacked by the disease, and will even itself soon communicate the infection to the brood. Experiment in such cases gives the most convincing results. Still, in the case of foul brood, as in the case of virulent affections which attack vertebrate animals, certain individuals seem to enjoy exceptional immunity, and resist the infection. Is this due to previous inoculations, or to some individual predisposition? This is a point which I am not at present prepared to decide.

"I had only once an opportunity of examining the queen of a hive infected with foul brood, the property of M. Matthey, of Bassins. The eggs of this insect were healthy, and contained neither bacilli nor virulent granulations. The queen herself was perfectly healthy, a point which I was able to place beyond a doubt by means of a careful post-mortem. I hesitate to draw any conclusion from this isolated instance, tho I confess that, judging from the course the disease takes, I do not believe that, as a rule, the malady can be propagated by the rearing of larvae produced from infected eggs.

"In my opinion, therefore, it is always the digestive canal of the nurse-bee which is infected, and it is always by the act of feeding that the adult bee infects the digestive canal of the larvae, the death of which latter is the speedy result of such inoculation.

"Therefore, a knowledge of the above facts leads me to the following conclusions:

"1. The bacteria of the third form described, as already

shown by Mr. Cheshire, are in effect the true cause of foul brood. They are the active agents of contagion and of the propagation of the disease. Numerous laboratory experiments, too long to be described here, prove this beyond the shadow of a doubt.

"2. Seeing that the foul-brood bacteria must necessarily kill all brood the digestive canal of which is inoculated by the act of feeding, it appears to be absolutely useless to endeavor to cure these larvæ, as all their tissues are rapidly invaded by the virulent granulations into which these bacteria resolve themselves. (I employ the word granulations purposely in preference to the term *spores*, which is used by several writers. I cannot bring myself to believe that true sporulation, similar to that observed under certain conditions in bacteria of anthrax, and in that of blood from spleen, really takes place in foul brood.)

"3. Adult bees, whose digestive canal is infected by the foul-brood bacteria, may frequently survive for a considerable period. Some even, owing to special circumstances, seem to resist the virulent stage of the malady. We must, therefore, direct our efforts to the digestive canal of the worker-bees, the feeders of the queen, if we desire to attack at its source the evil which may spread with lightning rapidity among the rising generation of larvæ, which is the sole hope of the colony.

"IV.—The treatment, then, ought to be internal and as energetic as our little patients are willing to allow. External treatment, by means of fumigations or sprayings of any kind, are (I do not for one moment deny) also helpful, since these methods contribute largely to the disinfection of the hives, combs, and tissues of the bees, etc. It is even possible, under certain circumstances, to succeed in diminishing the virulence possessed by the bodies of the larvæ after death during the process of desiccation. But I must repeat that such external treatment can only be useful as an auxiliary, and I greatly question whether it has ever been successful in curing of itself a colony attacked by a well-authenticated case of foul brood.

"The foul brood bacterium seems to be very fastidious with regard to the conditions of its existence. The media in which it can be developed are rendered sterile by the introduction of infinitesimal quantities of well known antiseptic substances. We are, therefore, justified in supposing that these same substances, if the bees can be made to absorb them, will prevent the invasion of the digestive canal and the surrounding parts by the bacillar bacteria, will destroy those that may have already lodged there, and will thus prevent the infection from spreading to the brood in the act of feeding.

"The space at my disposal is too limited to permit of a detailed description of the numerous experiments which led me to fix on an antiseptic of the first rank, introduced some years back as a valuable antiseptic remedy in the case of intestinal derangements in man. This substance is naphthol beta, which owes its introduction into general practice to the valuable researches of M. Bouchard, Professor to the Faculty of Medicine of Paris. This excellent antiseptic cannot injure the bees, and they take to it the more readily as it is not very soluble, and therefore is not easily absorbed by the intestinal walls. Notwithstanding this, even when administered in minute quantities—*e. g.*, in doses of 0.33 grammes to 1,000 of liquid, it effectually prevents all fermentation, decomposition, or other changes caused by the micro-organisms. The media most favorable for the development of foul-brood bacteria are rendered perfectly sterile when treated with a proportional quantity of naphthol.

"Lastly, thanks to experiments made with some full colonies partly attacked by the malady, which have been kindly forwarded to me by some of my correspondents, I have ascertained that a syrup medicated by a dose of naphthol in the proportions mentioned above is amply sufficient to rid foul-broody bees from the parasites contained in the digestive canal. In cases where the infection has not laid too strong a hold of the parts surrounding the intestine, the cure seems to be speedy and complete. Even in captivity and under very adverse sanitary conditions, the insects soon regain all their old activity and liveliness. The treatment which I venture to recommend to the serious attention of apiculturists is as simple and rational as possible:

"In the early spring, before eggs are laid, administer to the diseased colonies as large quantities as possible of sugar syrup containing 0.33 of a gramme of naphthol beta. The naphthol should be first dissolved in one litre of pure water, with one gramme of alcohol added to facilitate its solution. The liquid thus obtained is employed in making the syrup in the usual manner. I am quite certain that

with this dose the bees will readily take to the syrup, which is in itself a powerful antiseptic. I need scarcely add that first-rate hygienic conditions are also necessary if we desire to give the bees the vitality and recuperative power which play so important a part in enabling living organisms to resist the inroads of virulent microbes."—DR. LORTET, in the Bee-Keepers' Record.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Cleaning Drone-Brood Out of Combs.

A postal card from M. D. Andes, of Tennessee, gives a better way of cleaning out drone-brood than to have the bees do it. I wonder I did not think of it when replying, for I had tried it years ago and found it successful. Mr. Andes says:

DEAR DOCTOR: I have just read the question of Nebraska and your answer, on page 455. I had a colony this summer in the same fix as his. After shaking the bees off in front of another hive, I set the frames up by the side of the fence where I had about 100 young chickens, and in less time than it takes to tell it the drones and larvæ were gone, and combs clean. Just try it, some time. M. D. ANDES.

Purity of Stock.

If an Italian or albino queen gives you from 3 to 5 banded workers and black drones, would you consider such queens pure and all right? And in case you had young queens mated with such drones, wouldn't your bees be hybrids? Wouldn't such drones give you bees that were not pure? I am a queen-breeder myself, and claim that if the drones are black the queens are not pure. This is what I do: I sell all queens tested, and if the drones are black then I replace the queens. But you see, if my queens' mother is all right then I know I am right. I don't like Italian queens that give me black drones, or albinos, either.

ALBINO.

ANSWER. If the drones are black, I should not consider pure the mother from which they came. Not only that, but I should not consider that the mother of such queen was pure and purely mated.

Queen Superseded by a Virgin.

Will a virgin queen introduced in a hive containing a laying queen ever supersede the laying queen? Last spring, while looking over my hives, I found one containing queen-cells. As it was too early for them to swarm, I decided that they were superseding their queen. I closed the hive and in due time I examined them again and found no brood or eggs, so I gave them a frame of eggs and larvæ. A few days later I examined the frame I had given them, and found queen-cells.

About the time the young queen should have been laying I introduced a queen that had just emerged from a cell to supply them with a queen in case theirs had been lost on her wedding-flight. The next time I looked into the hive I think was about a week later. I found unsealed larvæ but no eggs; also a young queen showing the marks of fertilization the day before. I watch her carefully, and in due time she began to lay.

WISCONSIN.

ANSWER. Yes, bees will do almost all sorts of things about accepting or rejecting queens. I do not know that I ever heard of a committee of five workers entering an adjoining colony and taking home its queen, but almost anything short of that I should be willing to believe. Answer—

ing your question specifically, it would be nothing strange for an introduced virgin to supersede the laying queen under some circumstances. A virgin just out of the cell will be tolerated almost anywhere and at almost any time, but as she grows older she will in most cases be destroyed. If the old queen, however, is failing, or if it is about the close of the honey harvest, the younger may take possession. But in the spring-time, when there is in the hive a young and vigorous queen, you may count on the introduced virgin being destroyed 99 times out of 100. Yours was the 100th time.

Cyprian Bees.

1. Believing you have read the description of Cyprian bees in Bulletin No. 1, "The Honey Bee," by Frank Benton, I want to ask: Are they in *every respect* what Mr. Benton describes them to be? Is it a true and honest description of the Cyprian bee?

2. Can you tell where one may get queens of that stock of bees in their purity, unmixed with other bees? TEX.

ANSWERS.—1. Perhaps few are so competent to describe the different varieties of bees as Mr. Benton, and I know of no reason why he should want to misrepresent.

2. I don't know of any place where you can get pure Cyprians in this country. Whatever their virtues, they do not sufficiently overbalance their faults so that bee-keepers have wanted them. If they were better than other bees, you may be pretty sure the demand for them would secure a supply, and there would be plenty advertising pure Cyprians for sale.

◆◆◆
Bees in Observatory Hive—Queens of United Swarms.

1. I desire to place a frame of bees and queen in an observatory hive for about 6 or 7 days. I shall take this frame, etc., from a full colony. Will it be necessary to cage the queen when I put her back into her own hive? or how shall I manage without risk of losing her?

2. I united a small after-swarm with a fairly strong nucleus, putting the former into the hive occupied by the latter. On examining the combined colony subsequently I found one of the queens balled and nearly dead. Which queen would be most likely to be killed under the conditions? IOWA.

ANSWERS.—1. The probability is that she would be received all right back again, but if she is a valuable queen it might be well to cage her by way of precaution.

2. If the nucleus and the after-swarm were about equal in strength, the advantage would be on the side of the nucleus, because they were in their own home and the others were interlopers. More strongly still would the advantage be on the side of the nucleus if it had a laying queen, for the queen of an after-swarm is not a laying queen, and other things being equal the bees would prefer the laying queen.

Getting Rid of a Cross Colony, Etc.

1. May I object to your advice in a late number of the American Bee Journal, to leave bees in a hive where the combs are built criss-cross to the frames? I have just such a colony, *very* strong, and *very* cross. I dare not put my hand down to adjust the entrance-blocks, or blow smoke on them, unless protected by canvas gloves. Now, I want that queen out, but as I can't get the frames out to find and clip her, I don't want them to swarm, as there are tall maple and locust trees all around. A man might climb for a swarm, but I lost one last year with a Doolittle queen—a very large swarm—and I don't want to lose this. I have transferred several (four) colonies, but this one is too cross.

2. Would it do to put a hive with empty combs or frames of foundation and move that colony away, then in a few hours, when aware of their queenless state, give Doolittle cells, or simply a frame of brood from my breeding queen? Then 21 days later move again, treating the flight-bees the same empty combs and brood on the old stand. That would weaken it so that I could undertake to transfer, or I might give the transferred combs the last time.

By fall I would have three good colonies. I have already one from moving it, that is getting strong, but no surplus honey. In the spring the old colony will be changed by the new queen, and everything will be lovely, I hope.

3. This is the third year I have lived in hopes of a sur-

plus honey crop, but next spring, I will have them (the bees) all on Langstroth frames. I should be successful, for the men around here that put on 80 1-pound boxes in the spring, hive swarms, and take off boxes in November, more or less filled, get from 80 pounds to nothing; but there must be good forage or some would not store so well. Theoretically, I know more than they do, but practically I get no honey, and the only way I get any profit is by rearing a few queens that do wonders for others. They generally come to me to solve the "mysteries," and tell me later I was right—"that's just what they did!" but I want some honey. We used in our family of five, three 60-pound cans last winter, and wanted more.

I hope you will have a successful honey-flow, and build up your colonies to replace the loss you suffered last winter. (MRS.) PENNSYLVANIA.

ANSWERS. 1. Yes, decidedly you may object to the plan of leaving that colony of yours to swarm, altho the rule in general is a good one. But where it is too difficult to secure swarms it should not be followed, nor with stock so objectionable on the score of temper.

2. You are on the right track as to your plan of proceeding, with some variation. When you move away old cross-patch, don't wait a few hours before giving a frame of brood, for with nothing but empty combs or foundation the bees that go back to the old place may desert. When you set the hive in place of the one removed, have in it from the start a frame of brood, and it wouldn't be a bad thing to have a few young bees with it, for all the bees that come from the cross colony will be field-bees, unless you make the removal at a time of day when young bees from the old hive are out at play. Neither would a queen-cell be likely to be destroyed if given from the start. It isn't necessary to wait three weeks before making a second removal. Two weeks will do, and 10 days will give quite a supply of bees if the colony is strong; but of course you will have more bees by waiting three weeks. You say, "In the spring the old colony will be changed by the new queen," which sounds just a little as if you expect the bees themselves to change the queen by rearing a new one. If the queen is an old one, she is likely to be superseded this fall (less likely in the spring), but even if a daughter replaces the old queen, she is likely to inherit some of her mother's traits. It is just possible that if you interview the old colony about two days after moving it to a new location, you may not find it so very difficult to handle. The reduction in numbers, none but young bees being left, and the fact that no honey is being brought in, may have a taming effect on the colony that will make them like another colony.

3. There must be some reason why you don't get as much honey as some of the other bee-keepers that do nothing with their bees, while you manage yours with more intelligence. Isn't it possible that the explanation lies in the fact that they *don't* meddle with their colonies, and so they are allowed to be very strong, while you weaken yours by drawing from them? Possibly that isn't the reason; I only throw out the hint.

A private word in your letter makes me say not to worry that no acknowledgment was made for former replies. Altho it is pleasant to know that my answers are appreciated, yet that's what I'm here for, and one of the best ways to show that your questions are satisfactorily answered is to send on more.

◆◆◆
York's Honey Almanac is a neat little 32-page pamphlet especially gotten up with a view to create a demand for honey among should-be consumers. Aside from the Almanac pages, the forepart of the pamphlet was written by Dr. C. C. Miller, and is devoted to general information concerning honey. The latter part consists of recipes for use in cooking and as a medicine. It will be found to be a very effective helper in working up a home market for honey. We furnish them, postpaid, at these prices: A sample for a stamp; 25 copies for 40 cents; 50 for 70 cents; 100 for \$1.00; 250 for \$2.25; 500 for \$4.00. For 25 cents extra we will print your name and address on the front page, when ordering 100 or more copies at these prices.

◆◆◆
Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

United States Bee-Keepers' Association.

Organized to advance the pursuit of Apiculture; to promote the interests of bee-keepers; to protect its members; to prevent the adulteration of honey; and to prosecute the dishonest honey-commission men.

Membership Fee \$1.00 per Annum.

EXECUTIVE COMMITTEE. Pres., E. Whitcomb; Vice-Pres., C. A. Hatch; Secretary, Dr. A. B. Mason, Station B, Toledo, Ohio.

BOARD OF DIRECTORS. E. R. Root; E. Whitcomb; E. T. Abbott; C. P. Dadant; W. Z. Hutchinson; Dr. C. C. Miller.

GEN'L MANAGER AND TREASURER—Eugene Secor, Forest City, Iowa.

Place and Date of Next Meeting:

IN FRANKLIN INSTITUTE.

15 South 7th Street, between Market and Chestnut Sts., Philadelphia, Pa., September 5, 6 and 7, 1899. Every bee-keeper is invited.

VOL. 39. AUGUST 24, 1899. NO. 34.

NOTE—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound.

The Paper on Foul Brood, by Dr. Lortet, in this number, will be read with interest by those who desire to be fully informed with regard to foul brood, and especially by those who are in sympathy with the views held across the water. Authorities on this side do not take kindly to any drug treatment of the disease, but when such men as Mr. Thos. Wm. Cowan and M. Ed. Bertrand, the able editor of *Revue Internationale*, have faith in anything of the kind, it is at least worth while to know something about it. The paper in question was translated some time ago into English from the French, and is considered of so much importance that it was republished in the *Bee-Keepers' Record*.

A **Certain Question-Box** seems to have caused a little uneasiness in the editorial sanctum of the *Canadian Bee Journal*, if we may judge from this paragraph which appeared in the August number of our contemporary across the border:

A bee-journal with a question-box has above the department the following: "In the multitude of counsellors there is safety." Prov. xi: 14."

We have every respect for a question drawer and the answers to the questions, but as we have seen some of these departments conducted with such diversity of views and opinions, diametrically opposed to one another, it is a pretty difficult matter for a beginner to know what to pick out as best. The "safety" must consist in the fact that a great many have opinions diametrically opposed to one

another, and that the safety lies in accepting none of them with great certainty.

Of course, the criticism applies to the department in this journal, as no other bee-paper to-day, so far as we know, contains such a feature. As the experiences of those answering questions are varied, it must necessarily follow that their opinions based upon such experience would not agree exactly. Still, that does not prove that their disagreeing answers are worthless or unsafe to follow. One bee-keeper wouldn't use a bee-escape to remove honey; another wouldn't do without the bee-escape. Does that prove that the bee-escape is worthless? Other illustrations might be given, but it is hardly worth while. "In the multitude of counsellors there is safety."

Growing Basswood from Seed. Mr. A. I. Root is much interested in this matter, and has found that it is a hard matter to get the seeds to grow. Chas. Blackburn reports in *Gleanings in Bee-Culture* that in the fall of 1893 he planted seed in a pan. The next spring not one had sprouted, but in the spring of 1895 they began to sprout. In the spring of 1896, 40 or 50 came up; in the spring of 1897 they came up very thick; in 1898 a few more came up, and they were still coming up last spring. Mr. Root suggests hurrying their growth by cracking the seeds, dipping them in boiling water, or something of the sort.

Light-Weight Sections.—The editor of *Gleanings in Bee-Culture* seems to make a point in favor of selling sections by the piece, by saying that in good years it is going to be difficult to raise the price of honey if we sell by the pound, but less so if we sell by the piece. One can hardly see why there should be any reason for this, but the editor may be entirely right when he says:

"But the more honey is sold by the piece (and the practice is growing everywhere) there will be less and less deception; and the consumer will come to forget all about pound weights, and will simply ask how much that honey is per box or section—not how much it is by the pound."

Reports of Bee-Conventions. The *Canadian Bee Journal* very properly objects to the way in which so many reports of bee-conventions are made, in which is given perhaps the names of those present and the officers, that a profitable discussion took place upon a certain subject, but the profitable part, the discussion, is entirely left out. The *Canadian Bee Journal* is to be commended for giving a very full report of the discussions of the prominent bee-conventions in Canada.

Great Value of Sweet Clover. The often maligned yet immensely valuable sweet clover is slowly but surely winning its way into favor. The *Orange Judd Farmer*—one of the most influential farm papers in this country—speaks thus of sweet clover:

IS SWEET CLOVER VALUABLE?

To answer this question something must be known of the character of the plant. It grows spontaneously along tramped roadsides, even in the wheel-ruts in abandoned roadways, and in tramped or sodden land anywhere. When found in meadow-lands it appears not to occur except when the ground has been tramped by stock when wet. It grows by preference in old brick-yards. It may be grown in fields by proper tillage. Viewing it in no other light we thus see that sweet clover grows luxuriantly in places where few or no other plants flourish.

But it belongs to the great class of leguminous plants, which are capable, by the aid of other organisms, of fixing atmospheric nitrogen and storing it in the plant tissues (Ohio experiment station). It belongs with the clovers, and it may thus be used to improve the land upon which it grows, and this appears to be its mission. It occupies lands that have become unfitted for good growth of other

forage-plants. Its rank then is as a useful plant, capable of increasing fertility of land.

How shall sweet clover be treated? The plant is the farmer's friend, to be utilized and not to be outlawed. The plant grows and spreads rapidly. So do red clover, white clover, timothy, blue-grass and other forage-plants, but sweet clover grows where they do not. Its presence indicates lack of condition for the others. Viewed in this way it is to be treated as preparing unfitted lands for other crops. It may be mowed a short time before coming into bloom and cured for hay. Stock will thrive upon it if confined until accustomed to it. The roadsides, if taken when free from dust, may be made almost as profitable as any other area in clover by cutting the sweet clover and curing for hay. If this is regularly attended to while stock is kept from other lands that it invades, sweet clover will be found doing always the good work for which it is adapted.

We welcome the aid of the farm papers in the effort to acquaint the agricultural public with the many values of sweet clover. Some have been foolish enough to call it a "weed." Pretty good sort of weed, isn't it?

In many localities this year no honey at all would be harvested were it not for the sweet clover. It is not only the bee-keepers' chief dependence, but the farmer's ever-present and reliable friend. It will pay to cultivate its acquaintance, as well as the plant itself.

Serenading Swarms with Tin Pans. A correspondent says that the old custom of serenading swarms with tin pans originated from an old act of the English Parliament, giving a person a right to follow his swarm provided he rang a bell, or drummed on a tin pan, to give notice that he (the owner) was after the bees. This old act was past something like a thousand years ago, and during the centuries since it is evident that the original purpose of the drumming was lost sight of, and that subsequent generations came to the conclusion that the serenading induced a sort of spell on the bees, causing them to cluster so they could be captured. *Glesnings in Bee-Culture.*

The Philadelphia Convention, to be held Sept. 5, 6 and 7, in Franklin Institute, 15 South 7th Street, between Market and Chestnut Sts., promises to be the best ever held by the United States Bee-Keepers' Association, if we may judge by the excellent program arranged for the occasion. Also in view of the low railroad rates guaranteed to every one going to Philadelphia, Sept. 1 to 4 inclusive, there should be a very large attendance. The editor of the American Bee Journal and Dr. C. C. Miller, with other bee-keepers, will go over the Pennsylvania Lines, beautiful illustrations of whose entrancing scenery and elegantly equip coaches we had the pleasure of showing on our first page last week. Without doubt the Pennsylvania Lines run thru the finest country for scenic beauty to be found in all the East.

The Grand Army of the Republic holds its 33rd annual meeting in Philadelphia, Sept. 4 to 9, inclusive. Many bee-keepers are also old soldiers, and likely members of that splendid national organization of war veterans; all such, as well as other bee-keepers, should take advantage of the low rates secured by the G. A. R. people, and be in Philadelphia during the week of the Grand Army meeting and the bee-keepers' convention. The round-trip rate from Chicago, over the Pennsylvania Lines, is only \$16.45. That means you will be given a ride of 1,645 miles.

The best trains over the Pennsylvania Lines leave Chicago daily at 3:00 p.m. and at 11:30 p.m. Grand Army rates going are in effect Sept. 1, 2, 3 and 4. We expect to leave on the 3:00 p.m. train Monday, Sept. 4, which arrives in Philadelphia the evening of the next day at about 6:00 o'clock. We should be pleased to have any bee-keepers or

others west of Chicago go with us on that train. If you desire it, we will be glad to make any advance arrangements for you that you may wish, so that you can be sure to make connections with the train that leaves Chicago at 3:00 p.m., Sept. 4, or on the one starting at 11:30 p.m.

Mr. G. M. DOOLITTLE, of Onondaga Co., N. Y., reports as follows for the season of 1899, in the Progressive Bee-Keeper for August:

"Honey crop from basswood short this year. Honey not all off, but enough so that I can estimate pretty closely that the average will be from 40 to 50 pounds of section honey per colony."

MESSRS. W. E. HATTERMAN AND CHAS. BECK are two bee-keepers living about ten miles north of Chicago. We called on them Saturday, Aug. 12. Mr. Hatterman has 22 colonies run for both comb and extracted honey, and Mr. Beck about 30 colonies for comb honey. He expects to average 50 pounds to the colony, and retail it from house to house. The principal honey source this year is sweet clover. Mr. Hatterman thinks he will work for extracted honey exclusively hereafter.

Mr. R. F. HOLTERRIANN, for many years editor of the Canadian Bee Journal, feeling that he has received a "call" to go into religious work as an evangelist, has severed his editorial connection with that paper, and will "go wherever there appears to be an open door, to preach the word of God." He so announces in the August issue of the Canadian Bee Journal. We wish him abundant success in his future efforts, in a field which likely is not altogether a new one for him. A man can usually do his best work along the line to which he feels specially drawn.

PROF. A. J. COOK, of Los Angeles Co., Calif., spent Monday, Aug. 14, with us, when on his way back to his home in the sunset land. We fairly envy those California bee-keepers in having such a man as Prof. Cook among them. We wonder if they really appreciate him. We never before had a good opportunity to get acquainted with him, but now—well, it was a feast to be with him, and we only regretted his stay was necessarily so short; but he had to get back as soon as possible to take up the farmer's institute work which must be done before the term opens at Pomona College, where he is one of the honored instructors. What a pity he could not stay in the East long enough to attend the Philadelphia convention, and thus meet many of his old friends!

BARGAINS IN INCUBATORS. It is well known to readers of newspapers that prices generally have been advancing steadily of late, including those for labor, lumber and metals of all kinds. As a result, the prices of all manufactured articles must soon follow suit, including the prices of incubators and brooders. This simply cannot be helped; there is no way of getting around it. The Cyphers Incubator Co., Wayland, N. Y., therefore hereby give notice to interested persons that so soon as their new catalog and price-list for 1899-1900 is issued (which will be about Nov. 1 to 15) the prices of their incubators and brooders will be increased fully 20 percent. All who think favorably of buying a strictly first-class incubator this fall or next winter will find it much to their advantage to immediately correspond with the Cyphers Co., in order to obtain what is wanted at the present low prices. The fact is that the Cyphers Co. is in a position, just now, to save a limited number of customers from \$7 to \$18 net cash, depending on the size of machines bought. For full particulars, address the Cyphers Incubator Co., Box 50, Wayland, N. Y., not forgetting to say you saw their advertisement in the American Bee Journal.

The Dzierzon Theory. says Deutsche Illustrierte Bienenzeitung, so far stands as solid as a rock, and it will require more proofs than have yet been brought against it to budge it in the least.

Bees and Colors. R. Hamlyn-Harris says in the British Bee Journal that scarlet blossoms seem to be entirely ignored by bees. Blue, violet, and white are their pet colors. Yellow is less frequently visited, and green is treated with extreme indifference.

Celluloid Quilts seem to be in use in England, according to accounts in the British Bee Journal, giving an impervious covering thru which one can see. Glass has been used to a limited extent in England and in this country. Celluloid is also used for queen-excluders.

"**Draper's Barn**" is what the new hive on trial by the A. I. Root Co. and some others is playfully called. It is the same as a 10-frame Langstroth hive, only it is 2½ inches deeper. Its 10 frames are equivalent in comb surface to 12½ ordinary frames, and two of the "barns" hold more than three 8-frame hives.—Gleanings in Bee-Culture.

Putting Bees Out of the Cellar. Mr. Young says, in the Canadian Bee Journal, he does without paying any attention to where they are placed, and without putting out at different times. He says: "I start about 10:30 or 11:00, and when I get thru you would think they were swarming. I used to try a few to-day and a few to-morrow. Those you let fly to-day, to-morrow are ready to jump on the other ones."

Rietsche's Uncapping-Fork is highly spoken of in the German bee-journals as a better tool than a knife for uncapping. A writer in Elsass-Lothringischer Bienen-Zeuchter says the needles of the fork slip more easily under the cappings than the knife-blade; there is no tearing; uneven and tender combs are easily and quickly operated on; the fork works more easily and rapidly than the knife, and it costs less.

"**Plumping**" is a term used in the British papers, an explanation of which is kindly sent by Mr. H. Edwards. As used by Mr. S. Simmins, colonies in order are plumped by having given to them from other colonies all the brood they can care for, these other colonies being stimulated to fill up the places made vacant by the removed brood. The queens from which the brood is taken are thus forced to lay a larger quantity of eggs, and the colonies upon which "plumping" is practiced are earlier made ready for the harvest. The plumping begins with the strongest colonies.

How Long do Worker-Bees Live? About 45 days in the working season, says Doolittle, in Gleanings in Bee-Culture. About June 10, put an Italian queen in a colony of blacks, and in 40 days from the time the last black bee came out of its cell there will still be many black bees. On the 44th day very few indeed will be left, and in 45 days not one will be found in the colony. But a bee leaving its cell the first of October may live eight months, and in rare cases nine. The difference in the amount of work done makes the difference in the length of life.

Age of Combs. Leading bee-keepers of England seem to have a very different opinion from that entertained in this country as to the time when brood-combs become too old to be desirable. Says the British Bee Journal:

"We strongly advise the removal, every spring, of a couple of outside combs—choosing the oldest or most faulty ones, of course—and substituting frames fitted with full sheets of foundation. Then, after the bees have fairly started to build out the foundation, the frame may be placed right in the center of brood-nest without the slightest fear of chilled brood. By this means we get two new combs built every season, and by gradually renewing the whole

not only keep the brood-combs in good condition, but avoid faulty ones, and thus conduce to the comfort of handling workable frames when manipulating our hives."

That is equivalent to saying that in a 10-frame hive no frame should be suffered to become older than five years. On this side they would hardly be objected to on account of age if they were five times as old. Why this great difference on the two sides of the water?

Travel-Stain on Honey.—A. J. Wright indignantly denies in Gleanings in Bee-Culture that the dirty feet of bees have anything to do with travel-stain, or rather he denies that bees ever have dirty feet. He offers this very interesting method of determining whether their feet are dirty: Take a board not less than 10 or 12 inches square, tack on it a piece of clean white paper, and place it before a hive so that the bees will be compelled to travel over it on entering and leaving. If placed early enough in the morning and taken away each night before dew falls, he thinks it will be as white at the end of a long honey-flow as at the beginning. He thinks travel-stain is due to the neglectful habits of bee-keepers in not removing the old bottom-board with its dirt and litter, and replacing it with a clean one at the time of putting on sections, as he thinks this dirt is carried up by the bees and used in the cappings of the sections.

Handling Bees Without Smoke. Miss Gayton, prominent among the bee-keepers of England, never uses smoke in handling bees. Whether one who has a given amount of work to do in a given time could always afford to wait for bees to get in the proper frame of mind for easy manipulation is a question. But in many cases it might be useful to know how to get along without smoke. Miss Gayton says in the British Bee Journal:

"In 1879 I introduced my first Ligurian queens, and was delighted with the gentleness and activity of the Ligurian bee. I have not introduced any Ligurian queens since. The hybrids proved to be splendid workers, but require cautious handling, as they have not good tempers. I may mention that when manipulating I always don a bee-veil, but never use smoke, and find that bees are more gentle without it. Sometimes in autumn I use apifuge or a clean wet cloth over the hive, but I usually trust to letting light in gradually and only keeping a small part of the hive open at a time, and then, after waiting a few minutes, I go gently and quietly to work, the bees really retiring out of my way. If, however, anything has made a colony very irritable, I close it up at once and try another day, as I find if a colony is thoroly roused it takes a long time for them to become peaceably inclined again. If I can manage to do my work without causing the smell of the sting-poison to be noticed, I find no difficulty in handling the frames."

Miss Grayton depends upon letting in the light "gradually," and "waiting a few minutes." Adam Grimm practiced somewhat on the same line, but he took no account of the matter of light, simply "waiting a few minutes" for the bees to quiet down after being first disturbed, altho that "few minutes" sometimes was only a few seconds. Possibly the waiting allows the bees time enough to fill themselves with honey, or perhaps to begin filling with honey, for when a bee once begins filling with honey it is no light matter that will make it stop.

Langstroth on the Honey-Bee, revised by the Dadants, is a standard, reliable and thoroughly complete work on bee-culture. It contains 520 pages, and is bound elegantly. Every reader of the American Bee Journal should have a copy of this book, as it answers hundreds of questions that arise about bees. We mail it for \$1.25, or club it with the Bee Journal for a year—both for only \$2.00.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

The Premiums offered on page 541 are well worth working for. Look at them.

Root's Column

HONEY WANTED.

We are in the market for both comb and extracted honey. If you have any to offer, let us hear from you AT ONCE stating the grade, number of pounds of each grade, from what source gathered and HOW it is put up. If extracted, send a sample by mail.

We Handle

Several Carloads Every Year....

and may be able to refer you to a buyer if we cannot handle it ourselves.

See our ad in this column for July 6th issue for

Honey-Packages...

Five-gallon square Cans are now \$8.00 per ten boxes instead of \$4.00.

ADDRESS

THE A. I. ROOT CO.,
MEDINA, OHIO.

In the multitude of counsellors there is safety. Prov. 11 14.

Ventilation or Protection in Winter.

Query 101. Is ventilation or protection necessary in winter? If so, give one or more methods.—UTAH.

E. France—Yes, both. A proper answer would be too long for this department.

P. H. Elwood—The cellar seems to be necessary in this Mohawk valley (N. Y.).

Dr. C. C. Miller—Both necessary, but it would take all this page to give methods.

G. M. Doolittle—A good sized entrance for ventilation, and chaff hives for protection.

Dr. J. P. H. Brown—In my climate (Georgia) no extra preparation is necessary.

S. T. Pettit—Yes, to both. Space is too limited to do justice in these important cases.

A. F. Brown—That depends whether you live in Florida or Utah. Here in Florida it is not needed.

Prof. A. J. Cook—Not protection here in California, and ventilation only at entrance anywhere.

Eugene Secor—Yes, both, in my locality. Entrances wide open in a sufficiently warm, well-ventilated cellar.

E. Whitecomb—Protection is as necessary to bees as to stock. 1. Cellar-wintering, 2. Pack on summer stands.

J. M. Hambaugh—Both. This department will not give room to methods. Read some good, standard bee-book.

C. H. Dillbern—Yes, sir, in this climate (Illinois) it is, and in my opinion a good cellar is the best and cheapest protection of all.

Mrs. L. Harrison—Yes, to both. Protect from winds, and put some porous material above the bees, with a chance for the breath of bees to escape.

W. G. Larrabee—Yes I use a double-walled hive packed with planer-shavings, and a crate filled with shavings with cloth bottom to cover all in winter.

O. O. Poppleton—This is also a question of locality. In Iowa I preferred thoroly well-constructed chaff hives, with good windbreaks around the apiary.

C. Davenport It is in my locality, I winter my bees under ground, and usually give them ventilation by means of a pipe or tube running up thru the roof.

Adrian Getz Protection is absolutely necessary. So is ventilation. But this should not interfere with the warmth. A good sized entrance gives all the ventilation needed.

Mrs. J. M. Null—Rather indefinite. Both are desirable. Chaff hives answer admirably for out-door wintering, or ordinary hives protected on the same principle as chaff hives.

Rev. M. Mahin This is a very large question. Ventilation is certainly necessary in winter in all climates and conditions. The amount of protection in out-

METAL WHEELS
in all sizes and varieties, to fit any axle. They last forever. Either direct or stagger spoke. Can't break down; can't dry out; no resetting of tires. Good in dry weather as in wet weather. Send for catalog & prices. **ELECTRIC WHEEL CO.,** Box 17, QUINCY, ILL.

door wintering depends upon climate and the character. For many years I have not lost a colony that had plenty of stores and plenty of bees without any protection. I keep the entrances wide open. I live in Henry Co., Ind.

R. L. Taylor—Yes, ventilation always, and protection in some climates. Your question is scarcely intelligible. If you mean for bees in-doors, I venture a good cellar and absence of bottom-boards.

J. A. Stone—In central Illinois we think it is, as those who did not protect their bees last winter lost 50 percent of them. We put ours into the cellar and ventilated thru a window by a device that lets in the air but not the light.

R. C. Aikin—Yes, both. Protection to conserve heat, say chaff to absorb it and hold it. Chaff above, but so that air can freely pass thru it to completely carry off moisture. Ventilation and compact stores are ahead of protection.

J. E. Pond—I always winter bees on the summer stands, and I deem ventilation a necessity. I allow about 1/2 inch over the tops of the frames, covering with a cloth of some kind and filling over that chaff, dry leaves, or other absorbent.

Mrs. A. J. Barber—We have tried several plans for protection on the stands. We prefer the empty super on top of the brood-frames with a sack of sawdust big enough to fill the super laid in. This gives both protection and ventilation. We seldom lose a colony.

D. W. Heise—I like the hive well packed on the top, and sides if found necessary, but don't want much protection in the way of a windbreak. For ventilation I give 3/4 x 5 or 6 inches. This applies to outside wintering, of course, which I think the questioner has reference to.

J. A. Green—I think protection pays. I use packing boxes, six or eight inches larger each way than the hive, filled with leaves or planer-shavings. The only ventilation I care for is thru an entrance 12x3/4, so arranged that it cannot become clogged by ice or dead bees.

Emerson T. Abbott—I do not bother much about ventilation. Plenty of food in the right place, above the cluster, is the thing. Protection from sudden changes is an aid to successful wintering. Bees in a cluster do not freeze—they starve. (Dr. Miller, please take notice).

Dr. A. B. Mason—No, but both are a great benefit. My present method is to pile the hives one on top of another, 4, 5 or 6 high, without covers or bottom-boards in the cellar. I use a quilt of enameled cloth, and place sticks an inch square on top of each hive to set the next one on, leaving the cover on the last or top hive.

G. W. Demaree—In my locality (Kentucky) I winter bees on the summer stands. Plenty of stores, and just let them alone. The past winter, in February, my apiary survived eight zero days without a let-up—and during this unknown arctic spell for this locality, there were 36 consecutive hours that the temperature did not rise above the 10° mark below zero. At that time nobody expected to hear the "buzz" of a bee's wing any more; but the bees lived.

E. S. Lovesey—Yes, in all northern localities I believe both are good. Here (Utah) protection is good, but the bees must have sufficient ventilation to keep them dry. The bees appear to winter all right in a frost-proof house, and where there is no smelter smoke. As a rule, the bees winter fairly well with a little packing of chaff or lucern leaves over them, but one end of the cover should be raised about 3/8 of an inch; this will give them ventilation and keep them dry.

Hunting Bees in Trees.

On page 445, L. J. Clark asks for information about hunting wild bees. I am somewhat of a bee-hunter myself, and possibly my way might help him. It is as follows:

After bass-wood stops blooming (which in this locality is usually in July), I take some unfinished sections of light honey for bait, and three small boxes to catch bees in. I select a clear spot in the woods near some flowers where I can obtain bees. I divide a section into three parts, placing a part in each box. I then catch a bee in box No. 1, and place near a section outside, which I have for them to return to. Next I catch a bee in box No. 2, and then uncover No. 1, and so on until I have quite a number of bees returning, which usually takes about two hours. I think that's where some bee-hunters make a mistake, by not catching enough bees, and not giving them sufficient time to return and locate the bait. I find that they will return to the open section quicker than going into the boxes.

After they are working nicely on the bait, I procure my lines, there being some

Queens at half price

Balance of season. Select Tested Italian Queens, 1-100; Untested Italian Queens, 50 cents. Every Queen warranted to give satisfaction or your money back. Queens by return mail as long as they last. Address, F. A. CROWELL, 34A11 Granger, Minn.

They have also one of the LARGEST FACTORIES and the latest and most improved machinery for the manufacture of Bee-Hives, Sections, &c., that there is in the State. The material is cut from patterns, by machinery, and is absolutely accurate. For Sections, the clearest and whitest Basswood is used, and they are polished on both sides. Nearness to Pine and Basswood forests, and possession of mills and factory equip with best machinery, all combine to enable this firm to furnish the BEST GOODS AT THE LOWEST PRICES.

Send for Circular and see the prices on a full line of Supplies.

Don't fail to mention the Bee Journal when writing advertisers.

times two or three. I then start out to hunt, leaving the bait where it is.

If I fail to find the tree, I try another line if I have more than one. If I should fail on that, I would then go to the bait, take away the outside section, and open the boxes. By this time they will be working strong enough to enter the boxes. After quite a number of bees have settled in the boxes, I close them and move up a short distance directly on one of the lines. Then I open the boxes. In this way I get rid of the bees belonging to the other lines, and strengthen the line I am following. I seldom fail in finding them in this way.

A few points to be remembered: Use nothing but new, light honey for bait; catch plenty of bees, and give them plenty of time to return and locate. By this method, and by hunting their watering-places, I usually find a number every season.

JOHN PIDDINGTON.

Southern Wisconsin.

Drouth Lessens Honey Crop.

We are thru with our spring and summer crop of honey, having a very good yield from white clover, but we had a cool, rainy spell when the clover was at its best, which, coupled with the drouth that followed soon after, made us lose, I think, fully half of our honey crop; however, I am not grumbling, as there is a good prospect for a fall crop from aster. The drouth is broken now, as we had a light shower this morning, which with others we had about a week ago have brought the aster and other plants out wonderfully.

Mr. Peter Brickey, probably the oldest bee-keeper in this county, was laid to rest July 20. Mr. Brickey had been an active bee-keeper in his time.

J. WILEY MOUNTJOY.

Anderson Co., Ky., July 30.

Feels Much Encouraged.

I have been keeping bees five years, and this is the first time my hives have been filled. I have 22 good colonies, and will probably take off 1,200 pounds—some comb honey, but mostly extracted. I feel very much encouraged. I like the business, and I shall give more of my time to it.

E. B. LANGDON.

Douglas Co., Minn., Aug. 8.

Still a Little Foul Brood.

There are a great many in this county keeping bees who are not at all informed, who should take a bee-paper and read up.

This is my first year as inspector, and I of course have a good deal to learn. I find the bees in this county are in quite good condition, considering the cold and backward spring we had. We have a little foul brood, confined to one end of the valley, but hope soon to have it stamp out. We are using radical measures, hoping the sooner to get rid of it. We burn it—bees, hive and honey.

Owing to the cold, late spring there is quite a good deal of chilled brood, as we had it below the freezing point after the bees had started brood-rearing.

Our comb honey here is fit for a king—the finest in the country—and should bring more than the present price (9 cents.)

J. C. CARNAHAN.

Mesa Co., Colo., Aug. 6.

Bees Working on Melon Bloom.

[The following is a reply to Mr. Grant De Larm, of Platte Co., Nebr., written by Hon. G. W. Swink, of Colorado, who has had extensive experience with bees and melon-growing:—EDITOR.]

I don't think your bees would store much honey from the melon blossoms. We don't consider the yield of honey very much from melon bloom, but they get a good deal of pollen from it. Your bees will store a good deal of honey from a No. 1 sweet water-

melon, but it will be thin and dark, and I never thought it very good to winter bees on. But the bees would be of great value to the melon-growers, to fertilize the blossoms so the melons will set. We get 2 1/2 more cantaloupes now than we did before we had bees; and the same with water melons.

G. W. SWINK,

Otero Co., Colo.

White Honey Crop Short.

The crop of white honey is very short in this vicinity this season, but the prospects are favorable for a good crop of dark honey.

A. W. SMITH,

Sullivan Co., N. Y., Aug. 5.

Gathering Some Surplus Honey.

Lately the best colonies of bees have been gathering some surplus—and fair quality, not black stuff like last year. I just hear that Earl Baker, a young apiarist in the edge of the city, has been harvesting quite a lot—presumably sweet clover, which is plenty down there, and scattering this far out.

E. E. HASTY,

Lucas Co., Ohio, Aug. 7.

A Correction and Report.

Kindly correct the mistake in my fifth paragraph on page 515, where it reads, "The surface retains the heat," etc. It should read: The atmosphere above retains the heat, etc., and the warm atmosphere coming in contact with objects of the earth's surface, contract and give off moisture, etc.

Bees reduced from 60 colonies to 9, selling \$80 worth; 25 colonies froze during the severe winter, and 9 rousing colonies remain in 3-story 10-frame dovetail hives, full of honey and brood from top to bottom.

A. B. BATES,

Franklin Co., Mo., Aug. 18.

Laying Workers with Sealed Cells.

We had a laying-worker experience in our apiary this summer, that was very peculiar, and also very interesting. It occurred thus:

Two colonies cast a small after-swarm, one a black and one a beautiful hybrid, but no queen accompanied the blacks. The two were hived together. The young queen became fertilized and laid profusely for more than a month, but for some reason she suddenly disappeared, and some of the nicest queen-cells I ever saw were started. The strange part of the case was this: After the cells were sealed, laying workers made their appearance. As there were few or no drones in the hive, I thought perhaps those workers were laying to produce drones to fertilize the young queen, but, of course, as the eggs were not laid until after the queen-cells were sealed, the queen would perhaps be laying before the drones hatched. As I have said before, I thought

perhaps those workers were laying to produce drones to fertilize the queen, for I have no positive proof of it. Altho it does look doubtful that those would-be queens would know what their eggs would develop into when they were laying them, yet that is the conclusion I came to.

I was very much surprised also to find the bees starting cell-cups when they had as nice cells as they could wish. It has been stated by one of the most prominent beekeepers in the United States, that laying workers will never appear in a colony that has brood at the right stage for queen-rearing; this is, however, an exception to that rule. But what rule is there that does not have exceptions?

LATER.—Yesterday (July 29) I examined the hive. What great changes had taken place! The young queen had begun to lay, the laying workers had disappeared, and no trace of their work left except the corpse-like pupae which were dragged from the cells, and the milky juices being greedily devoured by the bees. Now, what do the readers of the Bee Journal think of such a colony of bees?

WILLIE T. STEPHENSON,

Massac Co., Ill., July 30.

HONEY AND BEESWAX MARKET QUOTATIONS.

CHICAGO, Aug. 19.—A few consignments of comb honey received this week, some cases of fancy in plain sections sold at 15 cents, other lots at 13 1/4-14 cents, while No. 1 sold at 12 1/2-13c; amber grades, 10 1/2-11c; dark, 7 1/2-9c. Extracted, white, 7 1/2-8c; amber, 6 1/2-7c; dark, 6c. All selling well. Beeswax, 25 1/2-26c.

R. A. BURNETT & CO.

KANSAS CITY, Aug. 19.—The receipts of honey are light, demand fair. We quote: Fancy white comb, 15c; No. 1, 14c; No. 1 amber, 12 1/2-13c. Extracted, white, 6 1/2-7c; amber, 5 1/2-6c; dark, 5 1/2-6c. Beeswax, 22 1/2-23c.

C. C. CLEMONS & CO.

NEW YORK, Aug. 9.—Old stock is entirely cleaned up, and good demand now for new crop. We quote: Fancy white, 13c; No. 1, 12c; fancy amber, 11c; No. 1, 10c. Extracted in good demand with market firm. Fancy Florida, 7 1/2c; choice, 6 1/2-7c; amber, 5 1/2-6c. Other Southern, 6 1/2-7c per gallon for choice, and 5 1/2-6c for common. No demand for buckwheat honey at this time. Beeswax dull at 24 1/2-25c.

HILDRETH & SEGELKEN.

SAN FRANCISCO, Aug. 9.—White comb, 11 1/2-12 1/2c; amber, 8 1/2-10c. Extracted, white, 7 1/2-8 1/2c; light amber, 6 1/2-7c. Beeswax, 26 1/2-27c.

There is not much offering, either here or at producing points. Market is firm at the quotations. Business is of necessity largely of a light jobbing character.

CLEVELAND, Aug. 18.—New honey scarce and in good demand. Fancy white, 15c; No. 1 white, 13 1/2-14c; fancy amber, 12c; No. 1 amber, 10 1/2-11c.

A. B. WILLIAMS & CO.

BOSTON, Aug. 18.—Fancy white comb, 1-pound sections, 15 1/2-16c; A No. 1, 14c; No. 1, 12 1/2-13c; No. 2, 10c. Light amber extracted, 7c. Beeswax, 27c.

The demand for honey is very light, as is usual this time of year. While stocks are extremely light, the old being practically gone, and no new as yet. Owing to poor crop prospects prices are firm, and it looks as if they would remain so.

BLAKE, SCOTT & LEE.

BUFFALO, Aug. 4.—The honey season has opened in a moderate way, a few small lots of new arriving. Extra fancy 1-pound combs, 13 1/2-14c; fair to good, 11 1/2-12c; dark, poor, etc., 8 1/2-9c.

BATTERSON & CO.

OMAHA, Aug. 16.—Still very little doing and receipts so light that a market price has really not been established. Little lots of choice new comb are still going at 14 1/2-15c, but a good many dealers will not touch it at these prices, and in order to place larger quantities at this time a considerably lower figure would have to be made. In the course of another month, when the weather is cooler and the taste for fruits more fully satisfied, the demand for honey will be more general and a more reliable market can be quoted. Extracted is slow sale at 7 1/2-8c.

PEYCKE BROS.

DETROIT, Aug. 19.—There has been no offerings of new honey and old is fairly well cleaned up. Fancy white we think would bring 14 cents, other grades proportionately cheaper. White extracted, 7 1/2-8c; no dark to quote. Beeswax in good supply at 23 1/2-24c.

M. H. HUNT & SON.

WANTED.—Comb and extracted honey; state price, kind, and quantity.

Foul Brood—Its Symptoms and Cure.

BY N. E. FRANCE.

FOU L brood is a contagious and fatal disease, dreaded most of all by bee-keepers, as the disease kills the bee in the larval age, usually from five to nine days from the egg of the queen-bee. The honey or combs from an infected colony contain the germs of disease, and, if left where bees can get to them, will be sure to spread the disease. Never buy or use old combs, hives, bees, queen-bees or implements from any apiary unless you are certain they are from healthy bees. Often have I traced the spread of the disease to such carelessness.

SYMPTOMS OF FOUL BROOD.

1. Colony or swarm of bees appear weak; do not protect the hive-entrance.
2. A part of the brood is dead, the cappings sunken and of a darker color. Ragged holes soon appear in the cappings.
3. At first the bee shows brown streaks, changing to a shapeless mass on the lower side of the cell, in color much like a cup of coffee when milk is added. At this stage it will be sticky or ropy, and if punctured with a stick will draw out much like warm glue.
4. There is a peculiar smell to foul brood in its advanced stage, much like old glue when heated. In many cases I have seen the odor was easily noticed several rods away.
5. Old, diseased combs will have some cells with the sunken cappings, underneath which there will be in some this brown, ropy substance; others will show it dried down to a black bunch at the front end of the cell, and still many other cells will have this dried down to a very thin scale, hardly noticeable. But in all these stages it will stick fast to the lower side-wall. Please

examine closely the accompanying picture of a diseased comb, containing all these stages described, taken from a large apiary where every colony had died with the disease.

TREATMENT OF FOUL BROOD.

1. The best time to cure foul brood is during the honey-gathering season; but, with great care and feeding, it can be done at other times. First of all, have a clean hive, a new one is best, but the old hive can be scraped clean, and, to be sure, I either boil the hive well, or paint it inside with kerosene oil, set afire, and, when well going, throw in some water and close the hive tight.
